$(y = 0$, giving $x = 0$ and $C_1 = 0)$.

Fig. 3.

In calculating the ordinates at the various points of the centre line the integrations are replaced by summations and the rise of the arches chosen as 34 feet; the ordinates and the horizontal pressure can then be obtained from the equation for y. H for this bridge is 345 tons.

The arches, having no hinges, are statically indeterminate in the third degree. The general form of the equations by which the three unknown quantities (X_a, X_b and X_c) are calculated, are with the usual notation

$$X_a\delta_{aa} + X_b\delta_{ba} + X_c\delta_{ca} = \Sigma P_m\,\delta_{ma} + \delta_{at},$$
$$X_a\delta_{ab} + X_b\delta_{bb} + X_c\delta_{cb} = \Sigma P_m\,\delta_{mb} + \delta_{bt},$$
$$X_a\delta_{ac} + X_b\delta_{bc} + X_c\delta_{cc} = \Sigma P_m\,\delta_{mc} + \delta_{ct};$$

δ_{at}, δ_{bt} and δ_{ct} being the influences due to variations of temperature.

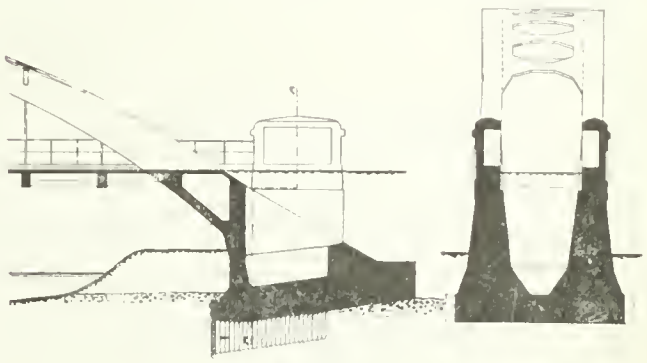

Fig. 5. Section A-A

From the theory of arches without hinges it is known that a very practicable statically determinate auxiliary system is obtained by introducing the normal force X_c, the transversal force X_b and the bending moment X_a at the crown of the arches as the statically indeterminate quantities and allowing them to act upon the arch from a point O (see Fig. 6) in the symmetrical axis of the arch determined by

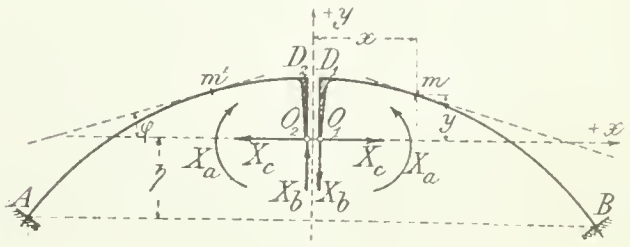

Fig. 6.

$$\delta_{ba} = \delta_{ab} = 0$$
$$\delta_{ca} = \delta_{ac} = 0$$

The equations for x will then be

$$X_a\delta_{aa} = \Sigma P_m\,\delta_{ma} + \delta_{at},$$
$$X_b\delta_{bb} = \Sigma P_m\,\delta_{mb} + \delta_{bt},$$
$$X_c\delta_{cc} = \Sigma P_m\,\delta_{mc} + \delta_{ct};$$

as $\delta_{cb} = \delta_{bc} = 0$, on account of the symmetry, and the statical determinate auxiliary system will be two curved beams with one fixed and one free end. (Fig. 6).

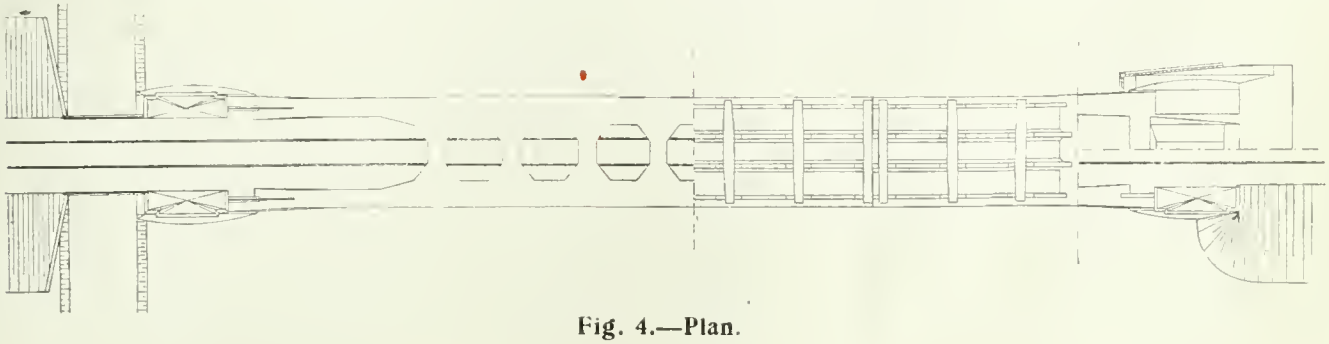

Fig. 4.—Plan.

The maximum bending moment and normal forces due to the live load in the various sections of the arches, are calculated by means of influence lines. The equations for the influence lines for the bending moment (M) and normal force (N) in the point m of the arches are:

$$M_m = M_{o,m} - X_a - X_b x - X_c y,$$
$$N_m = N_{o,m} + X_b \sin \phi - X_c \cos \phi;$$

$M_{o,m}$ and $N_{o,m}$ being the corresponding values in the auxiliary system, ϕ the angle between the x axis and the tangent at the point (Fig. 6), taken positive in the direction from the x axis to the y axis and the positive direction of the tangent taken toward the right. It will thus

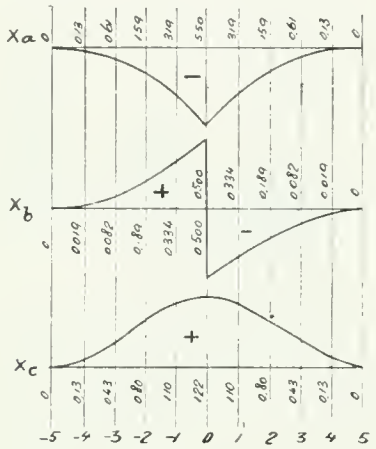

Fig. 7.

be seen that it is first necessary to find the influence lines for X_a, X_b and X_c, the equations of which, from the above given reduced equations, are:

$$X_a = \frac{\delta_{ma}}{\delta_{aa}}; \qquad X_b = \frac{\delta_{mb}}{\delta_{bb}}; \text{ and,} \qquad X_c = \frac{\delta_{mc}}{\delta_{cc}}.$$

wherein the different δ's are readily calculated by means of the so-called "v" forces. The influence lines for the quantities X are shown in Fig. 7, and the influence lines for the bending moments in Fig. 8.

A variation of the temperature of ± 40° F. was taken into consideration; the bending moments and normal forces produced by this change are:

$$M_t = - X_c y; \; N_t = - X_c \cos \phi,$$
$$X_a \text{ and } X_b \text{ being } = 0, \text{ and } X_c = \frac{\epsilon E t l}{\delta_{cc}}$$

in which ϵ is the elongation per unit length per 1° F., E the modulus of elasticity, t the variation of the temperature and l the span.

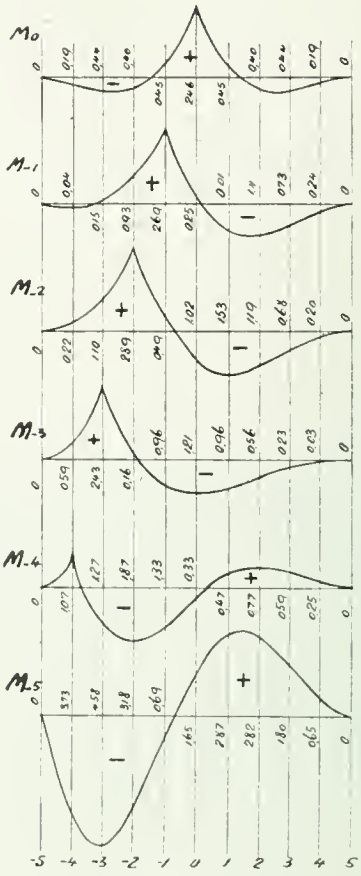

Fig. 8.

In Table I. is given the bending moments and normal forces due to the live load (M_p and N_p), to the dead load (M_g and N_g), and to the change of the temperature (M_t and N_t).

Table I.—Bending Moments (M) and Normal Forces (N).

Point.	0	1	2	3	4	5
Max. M_p	+ 34.8	+ 55.4	+ 61.7	+ 42.6	+ 40.4	+127.5 yard tons

From Table II., which gives the maximum stresses, it will be seen that the maximum compression stress in the concrete is 459 lbs. per sq. in., due to dead + live load, and 610 lbs. per sq. in. when the influences due to temperature variations are added. The allowable compression stress is nearly reached in all sections, while the tension stress in the steel has the maximum value of only 6,700 lbs. per sq. in., and the tension in the concrete 196 lbs. per sq. in.

Table II.—Maximum Stresses in Lbs. per Sq. In.

e = at extrados i = at intrados

Point.	Stresses due to p+g		Stresses due to

In order to prove the correctness of the results derived by the above described method of calculations, a careful test loading was arranged. Three railway trucks, weighing about 48 tons each when loaded with potash

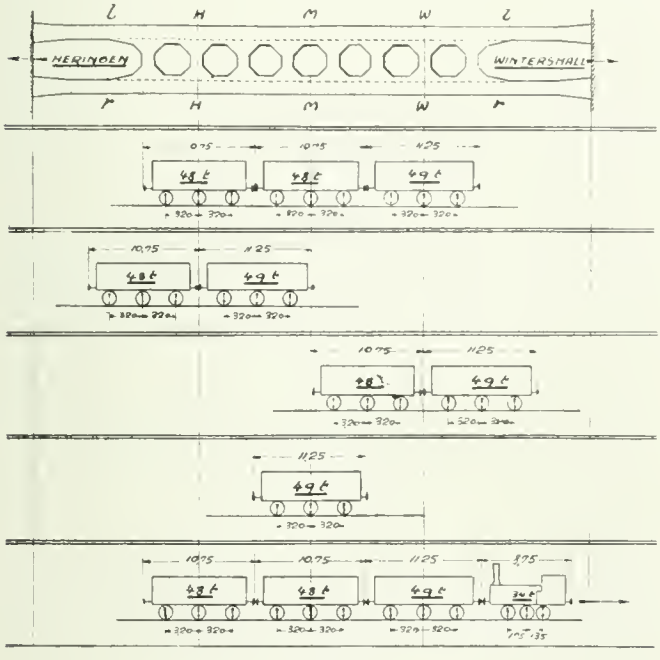

Fig. 9.

salts, and a locomotive weighing 34 tons, were used. Five different cases were examined (diagrammatically shown in Fig. 9):

(1) Three trucks placed symmetrically at the middle of the bridge.

(2) Two trucks, standing at the point at which the roadway is divided.

(3) The same as 2, at the opposite end.

(4) One truck at the middle.

(5) The whole train crossing the bridge at full speed.

The deflections were measured by means of wooden levers magnifying five times. Measurements were taken at both sides (called l and r in Fig. 9 and Table III.) in three vertical planes lettered H, M and W. The instruments were arranged in these three planes, not only under the bridge floor (called b) but also directly under the arches (a), so that the deflections were measured at twelve points in all. In Table III. are given the calculated and measured deflections. The results show a remarkably close agreement between them in all points, proving the possibility of computing correctly structures of this type. The modulus of elasticity derived from the test is 4,200,000 lbs. per sq. in., which is double that usually assumed in calculation. It must be remembered, however, that the concrete was five months old, and of

Fig. 10.

exceptionally good quality, being a 1:6 mixture of natural ballast from the Werra River with cement. Cubes of the same mixture gave a crushing strength of 5,100 lbs. per sq. in. after 28 days.

Table III.—Deflections in 1/25 of an Inch.

Loading Case	Side of Bridge	Location of Point	H Calculated	H Measured	M Calculated	M Measured	W Calculated	W Measured
1	l	a	+1.0	+1.0	+2.1	+2.2	+1.0	+0.7
		b	+1.4	+1.2	+2.9	+3.2	+1.4	+0.9
	r	a	+1.0	+1.0	+2.1	+2.2	+1.0	+1.2
		b	+1.4	+1.2	+2.9	+3.0	+1.4	+1.4
2	l	a	+2.5	+2.3	+1.0	+1.4	—1.5	—1.2
		b	+2.8	+2.0	+1.3	+1.3	—1.5	—1.2
	r	a	+2.5	+2.0	+1.0	+1.2	—1.5	—1.2
		b	+2.8	+2.2	+1.3	+1.4	—1.5	—1.2
3	l	a	—1.5	—1.2			+2.5	+2.4
		b	—1.5	—1.4			+2.8	+2.7
	r	a	—1.5	—1.2			+2.5	+2.6
		b	—1.5	—1.2			+2.8	+2.6
4	l	a			+1.7	+1.7		
		b			+2.5	+2.3		
	r	a			+1.7	+1.6		
		b			+2.5	+2.5		
5	l	a			+2.1	+2.4		
		b			+2.9	+3.2		
	r	a			+2.1	+2.4		
		b			+2.9	+3.2		

The deflections were calculated as bending moments produced by the "v" forces. The general expression for the "v" force, acting in the point m of the arch, is

$$V_m = \lambda M_m \frac{\sec \phi_m}{E J_m},$$

where λ is the distance between the points for which the "v" force is calculated (here 1/10 of the span), M_m is the bending moment, E the modulus of elasticity, J_m the moment of inertia at the point m, and ϕ the angle as defined above. In Fig. 10 is shown the influence line for the deflection at the crown; the figures written on the ordinates give the deflections in 1/25,000 of an inch for a force of one ton.

NOTES ON ELECTRIC FURNACES, WITH SPECIAL REFERENCE TO AN INDUCTION FURNACE.

THIS title has been given to the following paper, read at the 36th general assembly of the S.A.I. E.E., at Johannesburg on September 18, 1913, and written by Dr. W. Glucksman, D.Sc.:—

Before going into details of the induction furnace, I think it advisable to point out briefly the following facts. When heating a furnace by electricity the increase of temperature is due to the transformation of the electric energy into heat, either by the spark or by the arc which traverses the electrodes, or by a conductor according to the well-known law of Joule, i.e., proportionally to the resistance of the conductor and to the square of the intensity of the current. In accordance with the two means of the energy transformation we have (*a*) electric arc furnaces and (*b*) electric resistance furnaces. The electric current utilized under such conditions gives us the means of attaining far higher temperatures than are possible in the ordinary combustion furnaces, and has the valuable property of being easily regulated so as to maintain or vary the required temperature with a remarkable degree of precision. The use of electricity enables us also to concentrate the whole calorific energy in a relatively restricted space. In this connection I shall only remind you of Moissan's experiment, in which he concentrated 200,000 calories per second in the volume of one litre of titanic acid. Finally, the direct transformation of electric energy into heat is one of the most interesting properties of electricity, and it is owing to this property that we are able, in particularly advantageous conditions to utilize such natural sources of power as waterfalls.

In the manufacture of steel by means of an electric furnace one can start from cast iron and obtain as a result of the process any desired grade of steel, or if a more economical apparatus is available, we can use the electric furnace only in the last stage of manufacture. Naturally, to obtain the desired result we have to use one of the metallurgical processes ordinarily employed. In this paper we shall treat the electric furnace only as a handy apparatus for the manufacture of steel, for instance, without dwelling on its further valuable properties, which enable it to obtain results which cannot be obtained by any ordinary Siemens-Martin furnace.

Principal Types of Electrical Furnaces.—As I have stated above, two types of electrical furnaces are so far known, (*a*) arc furnaces and (*b*) resistance furnaces.

(*a*) *Arc Furnaces.*—Three different classes of arc furnaces are in use at present:—

1. Furnaces in which the bath communicates with one pole of the electric supply, the arc striking between the bath and one or several superior electrodes.

2. Furnaces in which the bath does not communicate with the electric source. The current enters through one or more electrodes and goes out through one or more other electrodes, after having produced as many arcs as there are pairs of electrodes.

3. Furnaces in which the arc is completely localized between the electrodes and is independent of the bath, the latter being heated by radiation.

The following are the types for the three categories of arc furnaces mentioned: The Siemens, Keller, Moissan, Stassano and Chaplet.

(*b*) *Resistance Furnaces.*—In the resistance furnaces heating is due exclusively to Joule's effect: $j = C^2 Rt$. Two classes exist. In the first the electric current passes directly into the metal to be melted; in the second the current passes into an auxiliary conductor, which heats the metal by conduction. These two classes are represented by Gin's canal furnace and the induction furnace. The idea of the induction furnace is due to Ziani de Ferranti, who patented it in Great Britain as far back as 1885. Ferranti's furnace is composed of an iron armature which has the form of a frame, and round one of its branches is wound a conductor, through which passes an alternating electric current. The secondary winding consists of a single spiral in short circuit, which amounts to a ring surrounding the other vertical branch of the frame. This ring is made of cast metal, is traversed by an induced current (the intensity of which is nearly equal to the primary current multiplied by the number of windings of the coil), and thus the transformation of electric energy into heat is made with the actual material to be heated. The Kjellin and Rhodenhauser furnaces are made on this principle.

Gassie's Induction Current Furnace.—The rapid progress of electric siderurgy revolutionized every metallurgical process. As yet we have no electric furnaces for smelting on the Witwatersrand gold mines, but the day is approaching when the electrification of the smelting furnaces will be an accomplished fact. It may be opportune to describe Gassie's induction furnace recently installed in Saint Jacques (France) with such striking success. This particular furnace is characterized by the low position of its induction coil, and principally by the use of specially selected materials in order to reduce to a minimum all eddy currents, loss due to hysteresis and dispersion. With this in view the armature was made of soft steel (silicon steel), which has a great resistivity and a very low coefficient of hysteresis.

The envelope of the masonry and also the parts which support the whole are made of non-magnetic steel, which contains 23 per cent. of nickel. The tub is naturally formed of several parts, insulated from each other, in order to avoid a closed metallic circuit through which only a portion of the current would pass. The refractory lining is made of either quartz in case of acid treatment or of dolomite and tar in case of a basic treatment. The core is formed of four branches, each composed of four bundles of sheet iron, separated from each other by a one inch air space for cooling purposes. Each bundle contains 105 pieces of sheet iron isolated from each other by a sheet of asbestos. The core weighs 12 tons. Its construction was a lengthy and delicate process, in view of all the precautions which had to be observed to avoid internal short circuits. The induction coil is composed of naked copper strips 1/8 inch thick by 3 15/16 inches long, assembled in twos to form a complete winding of 18 to 22 turns. An opening of 3/16 inch was left between each strip for the circulation of air for cooling purposes.

The Gassie's furnace avoids the use of circulating water for cooling, which is used in all other electric furnaces. Also the use of naked copper permits of easy variation in the number of turns in the coil. The simple alternating current of 16 cycles is provided by an inductor alternator of 400 kw., the load factor varying from 0.6 to 1. The excitation is provided by the power station at 250 v. The line which connects the alternator with the furnace measures some 60 feet. It is made of 12 copper cables of 0.19 inches cross section, spaced from each other in all directions by about 11.25 inches, the adjacent conductors being of opposite polarity. A room adjoining the furnace contains all regulating and measuring ap-

paratus, amongst which has to be mentioned an integrating wattmeter, which enables us to read at any moment the power consumed and also the power used for each operation of the process. The pressure in the primary does not exceed 300 volts and the intensity varies from 1,200 to 1,400 amperes.

Some Interesting Particulars During Reduction Operations.—The furnace under review treats 1.2 tons of steel. The chemical analysis during treatment can be made with perfect ease as compared with the old combustion furnace. The whole process, which can be started at a moment's notice. lasts two or three hours, and the energy consumed varies from 300 to 500 kw. hours per ton according to the metal treated.

Efficiency of Electric Furnaces.—It is most important to ascertain the efficiency of the electric furnace as compared with the coal or coke combustion furnace and to find the relative cost of electrical and fuel heat. In order to do so, we must consider in one way or another the amount of heat each type of furnace will generate, and what amount of electric energy will be required to be transformed into heat to produce as much as, say, one pound of coal would yield when being burnt. It is well-known that one kilowatt hour is equal to 3,415 British thermal units, and if we admit that one pound of best Transvaal or Natal coal on burning will give 12,000 to 14,000 British thermal units, we find that one pound of coal will be equal in calorific value to about 4 kw. hours. The first comparison seems not in favor of electric power, as we have to pay over a half-penny per unit, but in localities where water power can be developed cheaply, and also where the cost for transport of coal is high, electric power will be at once cheaper than coal. But the above comparison is superficial, incomplete and misleading, if we neglect consideration of the utilization of the heat generated. It should be borne in mind that the utilization of heat differs in an electric from that in a combustion furnace. The largest part of the heat generated in an electric furnace is actually utilized in heating the materials in the furnace, whereas in the combustion furnace this is not the case, particularly in one which requires a high temperature, the greatest portion of the heat being simply wasted and but a very small part actually utilized.

Before going into details I shall explain what I understand by the *efficiency* of a heating apparatus, such as a furnace. The efficiency is the ratio of heat units actually utilized in heating the contents, to the total heat units supplied either in the form of coal or electricity. In this connection the following table, prepared by Prof. Richards, will be of great interest, as it shows the typical efficiencies of the different furnaces:—

Crucible steel furnace	2 to 3%
Reverberatory furnace	10 to 15%
Regenerative furnace	20 to 30%
Shaft furnace	30 to 50%
Electric furnace	60 to 85%

These figures apply both for melting or smelting. A few words of comment will explain the above-mentioned table. In the crucible and reverheratory furnaces the greater part of the heat is carried away in the hot escaping gases. In the shaft furnace the heat is largely absorbed by the solid materials, mostly in the upper portions of the furnace. The furnace gases which are produced in electric smelting are very much less in volume than in combustion furnaces. Another point to be considered is the amount of atmospheric air that passes through the combustion furnaces in excess of that actually required to burn the fuel, which increases the already great loss of heat; and lastly, there is a serious loss due to incomplete combustion of fuel. All shut-downs, which are mostly inevitable, tend to lessen the efficiency of combustion furnaces, but the same does not apply to electric furnaces, as the supply of electrical energy is simply cut off. Thus, comparing the relative costs of electric and fuel combustion from the point of efficiency or useful work done, the electric furnace proves to be cheaper.

Experiments have been made, and it was established by actual measurements, that a much larger proportion of the heat generated electrically is transferred to the furnace charge than it is possible in a combustion furnace, in which the carrier of heat consists of a larger volume of gas, and in spite of all regenerative (Siemens) methods for smelting work, the method of heat transference by the individual hot gas molecules to the metal baths is a faulty one indeed. In the electric furnace, however, the main portion of heat is generated in the space intervening between the electrode and the slag, which space is less than an inch in width. The bottom surface of the electrode is at the volatilization temperature of the carbon, and thus a considerable portion of heat passes to the smelting charge by radiation, by means of carbon vapor. The carbon vapor, which starts from the electrode, is impinging continually on the surface of the slag, and is consumed by the slag oxides. In this way both fused materials, metal and slab, themselves form additional producers of heat. They further serve as resistance in the path of the current, and the layer of slag converts a very large amount of electricity into heat. The distribution of heat in the electric furnace is a long way the more economical. A most energetic reaction takes place in the space between the overheated particles of the slag, the electrodes and the constituents of the metal bath, which is the reason of the immense success of the operation. The rapidity of the work is due to the high current density, the enormous heat production in a narrow space, and the very great rapidity of the chemical reactions. All this produces an energetic mechanical flow of the liquid particles in the slag and the metal, which has a most favorable influence upon the desired change of constitution.

There will probably be many sceptics as to whether the electric furnace will supplant the different combustion furnaces mainly for smelting now in use on the Rand, but to those I would point out that at the end of 1910, France had only one electric furnace, and hardly twelve months later the number grew to thirty-five. Electricity has won the day everywhere, in spite of conservative opposition, and ere long war will be declared on the old combustion furnace, and I would recommend everyone to be on the side of the electric furnace.

The development of the natural gas areas in New Brunswick is proving a boon to the Intercolonial Railways. In the shops at Moncton it is used exclusively for the generation of power. The steady and reliable heat makes it an ideal fuel for the blacksmiths' forges, furnaces and gas engines. Being immediately ready for use there is no time wasted in "firing-up." Over 30,000,000 cubic feet of gas were used in September, and in the winter months 50,000,000 feet per month will be necessary to meet the railway's requirements, and results show considerable saving in expenditure. It is not generally known that this gas is used for the lighting of the railway's passenger cars all over the line.

EXTINGUISHING OF FIRES IN OILS AND VOLATILE LIQUIDS.

A PAPER dealing with the difficult problem of extinguishing fires in oils and in volatile liquids, has been written by Edw. A. Barrier, of the Department of Inspection, Associated Factory Mutual Fire Insurance Companies, Boston, for the American Society of Mechanical Engineers, New York. In his article, Mr. Barrier says that our most common extinguishing agent, water, works rather unsatisfactorily, and frequently disastrously, where fires of this kind occur; but concedes that it is still the only one available where heroic measures are required. However, two or three other materials have been introduced as extinguishers which have given promising results, and Mr. Barrier's paper is devoted to a discussion of these materials and to the conditions under which they prove most efficient.

It is only fires in volatile liquids where these are not miscible with water, in which water is of little or no effect, save to wash the burning liquid out of the building, where it may be consumed completely, or, if the quantity of liquid is small, where it may be extinguished by the brute cooling effect of a large quantity of water sprayed upon the fire. Where the liquid (such as denatured alcohol, wood alcohol, grain alcohol, acetone, etc.) is miscible with water, water may, of course, be used effectively. For non-miscible liquids, soda and acid are somewhat more effective, though non-infallible, extinguishers. However, only two principles can be relied upon in the extinguishing of fires in volatile oils—e.g., either to form a blanket of gas or of some solid material over the burning liquid so as to exclude the oxygen of the air, or to dilute the burning liquid with a miscible and non-inflammable extinguishing agent.

Mr. Barrier proceeds by discussing sawdust and bicarbonate of soda as blanketing types of extinguishers.

Ordinary sawdust is an excellent extinguishing agent for certain volatile liquids, especially those of a viscous nature. In the fall of 1912, experiments were performed by the inspection department of the Associated Factory Mutual Fire Insurance Companies, and fires in lacquer and gasoline in tanks were extinguished with sawdust with results both surprising and satisfactory.

The liquids were placed in three tanks 30 in. long, 12 in. wide and 16 in. deep; 48 in. long, 14 in. wide and 16 in. deep; and 60 in. long, 30 in. wide and 16 in. deep. The sawdust was applied with a long-handled, light but substantially built snow shovel having a blade of considerable area. In every case the fires were extinguished readily, especially in the two smaller tanks which were about as large as any ordinarily employed for lacquer in manufacturing establishments.

The efficiency of sawdust is greater on viscous liquids than on thin liquids; because it floats more readily upon the former. The sawdust is not easily ignited; but, when ignited, both burns without flame, and does not generate sufficient heat to reignite the liquid. Again, the character of the sawdust, whether from soft or from hard wood, is not an important consideration; neither is the amount of moisture contained in it; and thus the drying out of the sawdust when kept in manufacturing establishments for a time, does not effect its efficiency. However, the experiments showed that the admixture of bicarbonate of soda increases greatly the efficiency of sawdust, both by shortening the time of extinguishing and by decreasing the amount of material necessary. A further advantage of the admixture is that it decreases the possible danger resulting from the presence of sawdust in manufacturing plants. It would be difficult, probably impossible, to ignite the mixture through any chance carelessness.

Though the efficiency of the sawdust is greatest on viscous liquids, such as lacquers, heavy oils, etc., it was tested very satisfactorily also upon ignited gasoline, both contained in the smallest tank and spread upon the ground. Tests of the mixture conducted in larger tanks upon ignited thin liquids were unsatisfactory; since the sawdust sinks before the whole surface can be covered, and the exposed liquid reignites.

Another agent to which attention has been devoted in recent years is carbon tetrachloride. It is non-inflammable, non-explosive, and readily miscible with oils, waxes, japan, etc. When mixed with inflammable liquids, it renders them non-inflammable, provided a sufficient quantity is added. The specific gravity of its vapor is about 5½ times that of air; consequently it settles very rapidly. As an extinguishing agent, it both acts as a blanqueting agent—covering the burning liquid with gas or vapor—and dilutes the inflammable liquid, rendering it non-inflammable.

The use of carbon tetrachloride as an extinguisher has been explored chiefly by certain manufacturers producing extinguishers which use liquids; but the claims made for these extinguishers are, for the most part, grossly exaggerated, declares Mr. Barrier. None of these is more efficient than carbon tetrachloride, and none is the equivalent of ordinary water extinguishers for general use on such materials as cotton, wool, paper, oily waste, etc. However, Mr. Barrier allows that, on volatile liquids, oils, etc., carbon tetrachloride has shown very satisfactory results under some conditions, and allowing for the skill of the operator and the nature of the fire. For example, in tank fires the length of time that the liquid has been burning is an important factor; for, where the sides of the tank have become heated, the only way in which the fire can be extinguished is to squirt the liquid forcibly at the sides. To squirt it directly into the liquid makes extinguishing much more difficult, if not impossible.

A second important consideration is the height of the liquid in the tank. Where the liquid is low, the sides form a pocket which retains the vapor and aids considerably in smothering the blaze. When the tank is nearly full, however, this condition does not exist, and it is then very difficult, if not impossible, to extinguish a fire in a highly volatile liquid, such as gasoline; and only the most skilled operators are successful in these cases. Further, the size of the tank or the extent of the fire if upon the floor is, as would be expected, of considerable importance. In tanks larger than about 28 in. by 12 in., more than one extinguisher and operator working at a time are necessary to extinguish a fire in such materials as gasoline. In one test where a tank 60 in. by 30 in. was used no less than seven operators were necessary, and even then it was only with the greatest difficulty that the fire was put out.

Mr. Barrier points out that his remarks apply to carbon tetrachloride as generally sold in the ordinary one-quart extinguishers, and proceeds to consider the probability of greater efficiency from a larger extinguisher. This, however, would have to be specially designed to make it readily portable by mounting on a truck or some similar means. The writer then discusses a few systems recently installed in which an elevated tank containing carbon tetrachloride was connected with automatic

sprinklers or perforated pipes located in hazardous rooms where volatile and inflammable liquids are in use. So far as is known none of these systems has as yet been called upon to extinguish a fire, but there appears to be no reason why such a system should not provide excellent protection in special cases. In such systems it would be necessary to consider the safety of the workmen and furnish ready means of escape, since carbon tetrachloride is an anesthetic and where thoroughly sprayed through the air as from an automatic sprinkler it would probably produce rapid results.

The nature and effect of the fumes given off when carbon tetrachloride is thrown upon a fire is a subject which has received a great deal of discussion. When the liquid comes in contact with a fire the vapor is partly decomposed resulting in the evolution of a considerable quantity of black smoke which is undoubtedly finely divided carbon. Pungent gases are also produced which appear to be mostly hydrochloric acid with possibly a small amount of chlorine. Since carbon tetrachloride contains no hydrogen from which hydrochloric acid could be formed this substance must be produced by the action of chlorine on the gases arising from the burning material or upon the moisture of the air.

The fumes of carbon tetrachloride although of a very pungent nature do not produce any permanent injury under ordinary conditions where the operator can make his escape after he has inhaled all that he can stand, but they are a distinct handicap in fighting a fire and are one of the objectionable features to carbon tetrachloride as a general fire extinguishing agent. In large rooms or where a small quantity of carbon tetrachloride is sufficient to extinguish a fire the gases are of course less objectionable.

Mr. Barrier concludes his paper with the consideration of the method of extinguishing fires in oils and volatile liquids, recently proposed and experimented, e.g., the use of frothy mixtures. He considers the idea as a favorable one, the tests thus far reported having indicated satisfactory and promising results. The principle of this process the writer shows to be by causing two liquids to mix in a tank where foam is produced, by making the tank air-tight and then forcing the foam out by carbon dioxide under pressure and conveying it to the fire by means of a line of hose. However, no experiments have, as far as is known, been conducted in this country; and German scientists have not disclosed the exact nature of the liquids used. Yet, Mr. Barrier concluded with the statement that this method of extinguishing fires in oils and volatile liquids will undoubtedly prove to be by far the most efficient of any that has as yet been suggested.

NATIONAL ASSOCIATION OF PURCHASING AGENTS.

This new organization was formed in New York City on October 16th. Its membership will include purchasing agents and buyers representing some of the largest industrial corporations, railroads, steamship lines, street railways, gas and electric companies in New York, New Jersey, and Connecticut, The association has already a membership exceeding one hundred. H. T. Leeming, of Thos. A. Edison, Inc., is President, and E. B. Hendricks is Secretary-Treasurer.

The double-track electric railroad which is being built between Tokyo and Yokohama will be the most up-to-date in the Orient when finished early next year.

RAILWAYS AND MOTOR TRACTION.

THE following extracts from a paper by Mr. W. W. Hoy, general manager of South African Railways, read at the recent conference in London (Eng.) on motor traction, will be of interest in showing the possibilities of freight service to districts which, under ordinary conditions, would not have a railway line laid for many years.

In the course of his remarks, Mr. Hoy stated that the progress that has been made in constructing and perfecting road motor vehicles has been keenly followed by the South African Railway authorities, and the use of motor transport is regarded as a system especially suited to South African conditions, and should prove of great value for developing outlying districts sufficiently until the traffic offering justifies the construction of a line of railways, when the motor vehicles would be available for use in the development of other districts.

Attention was drawn to the fact that the South African railways are state-owned and motor services as feeders to the railways can be worked as branch services, the organization being as far as possible on railway lines.

Mr. Hoy pointed out how at one depot the postmaster controlled the motor staff and running details of service, whilst at others, duties were performed by the station master, thus ensuring economy.

As regards the most suitable type of vehicles, Mr. Hoy said, speaking generally, he was of opinion that for cross country freight traffic, powerful paraffin tractors with large and wide wheels would be most suitable. In most cases rubber-tired vehicles for heavy goods traffic could not be regarded as a practical proposition where transport had, in some cases, to be done at the rate of 4d. per ton per mile.

The average working costs for a paraffin tractor and trailers Mr. Hoy gave as follows:—

Average daily run (in miles), 15 to 30.

Average cost per car mile, including 20 per cent. depreciation, 4 per cent. interest, rent, insurance and supervision charges, 4s.

Cost per ton per mile, 5d.—3d. 15 to 30 miles.

Miles per gallon of fuel, 1.5 m. p.g.

Costing per car mile, 4s. 9d.

INCREASING PRODUCTION OF CEMENT.

According to the statistics contained in the report of Mr. J. McLeish on Economic Minerals and Mining Industries of Canada, the total production of cement in British Columbia in 1911 amounted to 401,000 bbls. valued at $601,500; in 1912 to 511,539 bbls., valued at $767,038; in Alberta for 1911 it amounted to 512,176 bbls. at a value of $1,241,535, for 1912 to 821,165 bbls., at a value of $1,775,898; in Ontario, for 1911, the production attained to 3,090,786 bbls., valued at $3,741,039, for 1912 to 3,044,713 bbls., valued at $3,372,897; and in Quebec, for 1911 the outlay was 1,614,730 bbls., worth $1,963,439, while for 1912 it was 2,714,685 bbls., worth $3,134,499. In each province is shown an increase in both production and the value thereof.

Eight years of labor and the expenditure of nearly $30,000,000 had their fruition on November 4th, when the water of the Los Angeles aqueduct, drawn from the high Sierras, 260 miles eastward, was turned into the big San Bernardino reservoir, 23 miles north of the city. Caravans of automobiles took crowds out to the reservoir, which was the scene of the initial features of a two days' celebration.

COAST TO COAST.

Regina, Sask.—The G.T.P. is operating another 100 miles of its new line through British Columbia.

Fredericton, N.B.—The Foundation Company, Limited, has completed its work on the Highway Bridge, and is shipping its plant to its next centre of labor.

Vancouver, B.C.—The matter of the formation of a water commission to take charge of the supply to Vancouver, as well as to the outlying municipalities, is being considered by Provincial Water Commissioner Young.

St. Thomas, Ont.—The three transformers for the new hydro-electric sub-station on the armory property, are being installed. This station is to supply several industries in the southern part of the city, and will relieve greatly the load on the main station.

Nelson, B.C.—Mr. W. P. Tierney, contractor for this portion of the C.P.R. Railway, announces that by December 15th the Kaslo and Slocan line, which is to provide railway connection between Kaslo, Slocan, the Arrow Lake and the coast, will be in operation.

Medicine Hat, Alta.—The new power plant was in operation the 23rd, 24th and 25th of October, and in the course of a few days will be put into permanent operation. In the Construction Department 2-10 K.W., 2-5 K.W., 2-2 K.W. transformers were installed.

Camrose, Alta.—While proceeding with drilling for natural gas at Camrose, the contractors have struck a 15-foot seam of coal. The coal is said to be of splendid quality, and was encountered at a depth of 400 feet. The contract for gas drilling calls for a depth of 1,500 feet.

Sault Ste. Marie, Ont.—Strenuous endeavor is being made to make sure the passing of the new drydock by-law. The $25,000 guarantee deposit has been placed in the Bank of Commerce. The people seem anxious to secure the new $10,000,000 industry, to which they will give a bonus of $20,000 per year for 20 years.

Edmonton, Alta.—On November 17th, 200 miles of new railway on the Canadian Northern Railway's western division were placed in operation. Of these 200 miles, 150 are in Alberta, and the remainder in Saskatchewan. These new stretches of railway provide new services between Alsask and Hanna, and between Drumweller and Hanna, in Alberta, and from McRorie to Elrose, Sask.

Ottawa, Ont.—Mr. J. D. McArthur, contractor for the Hudson Bay Railway from Le Pas to Port Nelson, stated while in the capital that over 159 of the 420 miles to be graded have been completed; and that before the season's operations cease, steel will have been laid on 130 miles of the grade. At the end of next season, Mr. McArthur hopes to have reached Port Nelson with the grade.

Port Arthur, Ont.—It is expected to complete the connection of the Sudbury-Port Arthur section of the C.N.R. before the end of December, and, if necessary, a freight service may be run over the line during the winter. The first passenger train will run some time during the summer of 1914. To lay the line from Ruel to Port Arthur, a distance of about 500 miles, will have taken approximately two and a half years.

Fort William, Ont.—The Mission River has been officially declared open for navigation. Captain McAllister, harbor-master, and W. P. Merrick, harbor engineer, performed the ceremony by placing the spar buoys marking the channel from the mouth of the river out into the deep lake water. The dredging of this channel was started early in the spring, and has resulted in a passage 600 feet wide, 25 feet deep, and extending over 1,400 feet.

Medicine Hat, Alta.—The report of the city health officer on the water supply, dated October 31st, declares that analysis of city water has shown it to be almost entirely pure. There are contained only small quantities of harmless salts and lime, aside from traces of silica, aluminum and oxide of iron. The colon bacillus (typhoid germ) was entirely absent, while the bacterial count was 118 per cubic centimeter, which is remarkably low.

Redcliff, Alta.—Mr. R. Wray, superintendent of the Gas and Light Company, has stated that within a few days the south end of the town will be connected with the new gas well on the river bank, and will be supplied with a uniform pressure equal to that enjoyed by the rest of the city. This year, moreover, the company expect to accomplish the laying of 26,340 additional feet, or five miles, of pipe, and the gas building is now practically ready for occupancy.

Medicine Hat, Alta.—Two new gas wells were completed during the month of October, one in the West Industrial Site and one in Harlow Fuller Subdivision, and up to date these wells are satisfactory, the Harlow Fuller well being an especially good one, the capacity being over 3,000,000 cubic feet for 24 hours and the rock pressure approximately 550 pounds per square inch. A well in Block 5, Cousins & Sissons' Subdivision, is under course of construction at the present time.

Galt, Ont.—It is expected in Galt that the C.P.R. double-tracked main line will have reached there before 1915. The track is already in operation between West Toronto and Erindale; and work is proceeding satisfactorily to Guelph Junction. Tracks have been laid, but the new roadbed has yet to be ballasted. The work, however, cannot be carried much further than Galt next season; for several natural difficulties, such as rock cuts and deep gullies, will force construction to progress much less rapidly. Considerable time will be required before the road has reached Woodstock and London.

Winnipeg, Man.—A special announcement to the Winnipeg "Weekly Beacon" from Mr. Collingwood Schreiber, the Dominion Government's chief engineer, says: "The golden spike of the Grand Trunk Pacific Railway will be driven near Fort Fraser, B.C., early next summer. By April the grading of the line will be completed." Less than 300 miles remain to complete the connection of the Transcontinental Railway. Either the Duke of Connaught or Premier Borden is to drive the final spike; and old No. 1 engine, of the G.T.R., still on duty as a shunter in the east, will pull the first through train over the new road from old Ontario to the Pacific Coast.

Ford, Ont.—This new city is distinguished by the fact that the foundation for a mammoth producer-gas engine has been finished here. The engine is to supply power for the Ford Motor Company plant in Detroit. The length of this latest creation in power plant engine building is 73 feet and its overall width is 32 feet. The crank shaft is 32 inches in diameter, 25 feet long, carrying an 80-ton fly-wheel and a 2,500 kw. generator; armature and the connecting rods weigh 10,300 pounds each. The generator is capable of carrying a 25 per cent. overload, and the engine has a capacity of 5,000 i.h.p. Work on this new power plant is being rushed as the capacity of the present generating apparatus is much over-taxed.

Victoria, B.C.—As a result of the settlement of the earth beneath the pavement on Oxford Street, between Linden and Moss Streets, the big brick sewer constructed along that street three years ago has caved in, the pavement above has collapsed, and damage which will require an expenditure of approximately $8,000 to repair, has been done. The street, when the roadway improvement was made, was graded up

to the requisite level, and apparently this new earth, with the action of the water which has drained beneath the pave-base has settled the earth, the pressure on the sides of the brick sewer beneath causing the cave-in on that work. The lack of support beneath the pavement has allowed that part of the street work to settle.

Montreal, Que.—Mr. R. P. B. Motley, the chief engineer of bridges for the C.P.R., said, in reference to the Lachine bridge construction, that three years had been necessary for the work owing to the fact that the traffic over the bridge on the single track was not delayed for a moment throughout the entire time of erection. In reality there were two bridges, each of single track, and by well-considered methods the structure was erected in sections—traffic being shifted from up stream to down stream until the bridge was completed. The bridge is now open for double-track service, and will be of immense convenience and benefit in the operation of traffic in and out of the Montreal terminals. The Lachine bridge adds another to the many engineering triumphs the C.P.R. has realized since its inception—the necessities of the original survey, especially in the West, compelling the company to build almost countless bridges as it went along, which early gave the company a deep interest in efficient designing and bridge building.

Saskatoon, Sask.—Engineer Clark has reported to the city council concerning the flow of quicksand on Long Hill slide the following: "The driving of the steel sheet piling was completed on Saturday, October 25th, and during the following week excavation was being made through the quicksand layer down to clay for the purpose of placing boulders. This had been accomplished for about one-half the total length when towards the east end of the piling the layer of sand became thicker and apparently dipped into the face of the hill. The removal of part of the top dry soil which was necessary in order to determine the conditions existing, allowed the running sand to flow so freely that excavation was at once stopped and arrangements were made to drive sheet piling to prevent a further flow of sand until the excavation could be made. The seriousness of this situation is understood when it is explained that the sand was apparently flowing from underneath the end of the retaining wall. The work of driving the sheet piling is well under way. Mr. Clark, however, would not state positively that the driving of sheet piling will stop the flow permanently.

Vancouver, B.C.—The work on the new station in connection with the terminal improvement scheme for the C.P.R. is progressing favorably. It is expected that the east section of the new depot will be ready for occupancy by Feb. 1st. The new building will, when erected, be an imposing structure, with massive Corinthian columns adorning the facade, and with stone cornices and trimmings enhancing its general appearance. The building will extend almost two blocks along Cordova Street, from the middle of the block between Seymour and Richards to Granville Street. It will be of the most up-to-date and substantial construction, strongly reinforced with steel, with concrete floors and solid pillars. The retaining wall in front of the depot, built in order that the tracks may be raised five feet from the present level, is now nearly finished. A railing to separate the passenger tracks from the yards and freight lines will surmount the wall. The change in the grade will result in a greater elevation for the entire station layout, leaving the other tracks on the present level. The girders for the station shed, which will jut out from the main building, are now being placed in position.

Victoria, B.C.—The Provincial Government has expended this year the gigantic sum of $4,000,000 on road extension and improvement work, according to the recently issued statement of the Hon. Thomas Taylor, minister of public works. The present length of roads and trails in British Columbia is 18,000 miles; and the sum required for maintenance has increased, and will increase, rapidly, owing to the additional mileage, and to new conditions which have arisen during the past few years. Upon bridges, which are generally classified under the heading of road improvements, the sum of $900,000 has been expended by the provincial works department this year, with $50,000 for wharves, and $70,000 for road location work. On road machinery, of which the most up-to-date types have been secured, the expenditure was $100,000. The road construction of particular interest was, however, the Banff-Windermere road. When it is finished there will be in existence a fine, circular 500-mile auto highway running from Calgary through to Banff, across the boundary line to Castle Mountain, south to Sinclair, further south to Fort Steele, thence east through Southern Alberta, and north again to Calgary via the Alberta roads, parallel to the Calgary-Macleod Railway line. Every link in this great highway is now in use except between Castle Mountain and Sinclair, a distance of seventy-two miles, of which about thirty-five miles of roadwork has been completed, leaving less than forty to finish next year. It is generally believed that with a sufficient appropriation from the Legislature next year, and good working conditions, the highway link referred to will be finished before the end of 1914. Great progress has been made in connecting the different district trunk roads into one main road to traverse the province, over $100,000 being spent upon the Hope-Princeton connection, while through the Similkameen, Grand Fork, Greenwood, Ymir, Fernie and Cranbrook districts, splendid progress has been made with standardization work.

Vancouver, B.C.—Mr. Sidney Billington has written an interesting sketch concerning the opening up of the Fort Fraser district and the linking up of the Transcontinental line between the east and the west, now rapidly nearing completion. The following is an abridged quotation: "Boundless farm, forest and mines in the northern interior of British Columbia will be thrown open to hundreds of thousands of settlers next year when the transcontinental line of the Grand Trunk Pacific Railroad will have direct communication between Prince Rupert, the western terminus, and the eastern maritime seaboard. The only remaining link to be completed is represented by a comparatively few miles in British Columbia, and there is every assurance that the contractors will complete their stupendous task before the end of the summer of 1914. With few exceptions, indeed, the grading is now completed and the worst of the canyons which disputed the progress of the bands of steel have been spanned. Mineralogists and agricultural experts are agreed that the section of British Columbia through which the line passes contains tremendous values which will amply repay those who undertake the development. Logical trade centres are being established along the route, and many of these will be invaluable to miner and agriculturist alike. A disputed point is, however, the possibility of too many townsites being instituted. With Fort Fraser, the situation is entirely different. It has no opposition. The town is growing up on absolutely fixed lines, and will draw on the largest stretch of agricultural country anywhere in British Columbia. Anything that will grow outside the tropics has been raised to perfection in the Fort Fraser district, and the average crops per acre are large enough to show highly satisfactory returns, giving handsome profits on the time and capital expended. And now, where a year ago stood a pre-emptor's hut, a town is daily growing into an active commercial centre. With an unlimited supply of water power for hydro-electric purposes, Fort Fraser will attract many large industrial concerns, which, being on the ground, will have the advantage over freight rates and be enabled to successfully compete with the manufacturers in east and south."

PERSONAL.

LEONARD W. RUNDLETT, city commissioner and city engineer of Moose Jaw, Sask., has tendered his resignation, to take effect January 1st, 1914.

FRANK B. GILBRETH, consulting engineer, New York City, addressed a large meeting of the Engineering Society on November 12th on one of the numerous phases of the subject of "Scientific Management."

GEORGE SERVICE, consulting engineer, of Toronto, has become associated with the Dominion Power and Transmission Company, Limited, Hamilton, taking charge of the construction of their new steam plant.

C. J. McLAUGHLIN, of the United States Department of Health, Washington, is working in conjunction with Dr. J. W. S. McCullough, Provincial Officer of Health for Ontario, in the preparation of an exhaustive report on the "Pollution of Boundary Waters" to be made to the International Waterways Commission in the course of a few days.

JOHN B. ARMSTRONG, for several years in charge, as chief engineer of construction, of the building of the Hudson Bay Railway, has tendered his resignation to the Government. He purposes engaging in contracting. It is stated that J. PORTER, who has been on the construction of the National Transcontinental Railway, will succeed him.

OBITUARY.

The late Mr. JAMES MELVILLE ROBERTSON, A.M.I.C.E. and A.M. Can. Soc. C.E., who was accidentally killed by the discharge of a rifle at Sylvan Lake, Alberta, on the 14th of September last, was the only son of Mr. and Mrs. James Robertson, of Bonneybridge, Stirlingshire, Scotland He was 27 years of age, and received his earlier education and training for the profession in Glasgow, Scotland, being a graduate of the Glasgow West of Scotland Technical College, and afterwards a pupil of Messrs. Wharrie & Colledge, Civil Engineers, Glasgow. His experience subsequently has been principally on Canadian railways. By his great zeal for his work and thoroughness in the execution of his duties, he rapidly gained the confidence of his employers, and at the time of his death held the position of resident engineer on the construction of an important part of the Alberta Central Railway, which included the building of the large bridge across the North Saskatchewan River at Rocky Mountain House, Alta. He was a young man of sterling character, with bright prospects for the future, and made for himself many professional associates.

THE AMERICAN INSTITUTE OF ARCHITECTS.

The 47th annual convention of the American Institute of Architects is to be held in New Orleans, La., on Dec. 2nd, 3rd and 4th.

1914 CONGRESS, AMERICAN HIGHWAY ASSOCIATION.

Knowing well the benefit of the impetus to good roads throughout surrounding territory which the American Road Congress affords the city in which it is held, some fifteen of the leading cities of the United States are vigorously contending for the 1914 Congress. While no decision has yet been reached, it is indicated that the contest is principally between Atlanta, Denver and New Orleans. It is stated that San Francisco, Spokane and Los Angeles are campaigning vigorously to secure the Congress for 1915, the year that the opening of the Panama Canal will be celebrated on the Pacific Coast.

THE DRIVING OF MOUNT ROYAL TUNNEL.

The Engineering Alumni Association of the University of Toronto held its first meeting for the season on Monday evening, November 17th. Mr. S. P. Brown, Managing Engineer, Montreal Tunnel and Terminal Company, addressed the meeting on the "Mount Royal Tunnel." His talk was well illustrated by numerous slides, descriptive of the engineering features of the work, and comparative of this great undertaking of the Canadian Northern with the Pennsylvania Tunnel and the New York East River Tunnel. About three hundred members of the Engineering Alumni Association were in attendance, while the Toronto Branch of the American Institute of Electrical Engineers were also present to the extent of about twenty members.

CANADIAN SOCIETY OF CIVIL ENGINEERS, VICTORIA BRANCH.

On Nov. 13th, the Victoria Branch was addressed by Mr. H. A. Icke, who spoke upon "Some Disregarded Stresses in Reinforced Concrete Design." The next assembly is the annual meeting on Dec. 11th, when Mr. F. C. Gamble will give an address, entitled "Some Engineering Works in British Columbia." The annual election of officers will also take place at this December meeting.

ANNIVERSARY DINNER.

The University of Toronto, Engineering Society, announce the date of their Annual Dinner as Friday evening, December 5th. The event is being held in honor of Dean Galbraith, this being the fiftieth anniversary of his entrance to the University of Toronto as a student, and the thirty-fifth anniversary of the founding of the School of Practical Science, which, seven years ago, became associated with the University of Toronto as the Faculty of Applied Science and Engineering.

COMING MEETINGS.

AMERICAN INSTITUTE OF ARCHITECTS.—Forty-seventh Annual Convention, to be held in New Orleans, La., December 2nd, 3rd and 4th.

AMERICAN SOCIETY OF REFRIGERATING ENGINEERS.—Annual Meeting will be held in New York, December 2nd to 5th. Secretary, W. H. Reed, 154 Nassau Street, New York City.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—The Annual Meeting will be held in New York, December 2nd to 5th, 1913.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS.—Annual Meeting to be held in New York, December 10th to 13th. Secretary, C. D. Odsen, Polytechnic Institute, Brooklyn, N.Y.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS.—Seventh Annual Convention will be held at Great Northern Hotel, Chicago, December 29th to 31st. Secretary, I. W. Dickerson, Urbana, Ill.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found sommaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20758—November 7—Approving location Glengarry and Stormont Ry. Co.'s line from mileage 0 to 24.05.

20759—November 6—Relieving C.P.R. from providing further protection at crossing of Godfrey Avenue, Winnipeg, Man.

20760—October 30—Refusing application of S. J. Blair, Calgary, Alta., for an Order staying proceedings under Order No. 19075, dated April 16th, 1913, and for permission to re-open matter of application of C.P.R. for authority to construct branch line for Northern Electric and Manufacturing Co., Limited, Calgary; but that Order authorizing construction of said spur be not construed as giving effect to said consent as will any way prejudice Applicant from hereafter claiming that Ry. Co. cannot construct said spur over land of Applicant without first taking expropriation proceedings under provisions of Railway Act.

20761—October 30—Granting application city of Calgary, Alta., for an Order directing C.P.R. to provide suitable level crossing where Calgary and Edmonton Ry. intersects 32nd Avenue: crossing to be constructed in accordance with Standard Regulations, and at expense of city.

20762—November 5—Granting application Rural Mun. of Fort Garry, Man., for an Order directing C.N.R. to provide proper culvert under its tracks where same cross Waller Avenue; culvert to be constructed at expense of said Rural Mun. of Fort Garry.

20763—November 5—Granting application Rural Mun., Fort Garry, Man., for an Order directing C.N.R. to provide crossing over said Ry., at Southwood Avenue, said municipality, at expense of municipality.

20764—November 4—Amending Order No. 20018, dated August 14th, 1913, by providing that cost of maintenance of watchman employed at crossing of Anderson Street, town of Grenfell, Sask., be apportioned as follows:—60 per cent. by C.P.R. and 40 per cent. by municipality of town of Grenfell.

20765—October 31—Directing that C.N.R. file with Board within ten days from date of this Order, plan in triplicate of a freight shed 30 x 40 ft., to be erected at St. Albert, Alta., Ry. Co. erect same within 30 days after approval of said plans.

20766—November 5—Granting application of Rural Mun. of Fort Garry, Man., for an Order directing C.N.R. to provide crossing over its tracks at Chevrier Boulevard, at expense of said municipality of Fort Garry.

20767—November 5—Granting application Rural Mun., Fort Garry, for an Order directing C.N.R. to provide crossing at Waller Avenue, at expense of said municipality of Fort Garry, Man.

20768—November 1—Dismissing application city Saskatoon, Sask., for an Order for leave to construct highway across C.P.R., at Avenue J, said city, by carrying Avenue J across at rail level.

20769—November 1—Granting application city of Saskatoon, for an Order to construct highway across C.P.R., at rail level, at Avenue I, said city, at its own expense.

20770—October 31—Finding and adjudging that title of Ry. Co. (Calgary and Edmonton Ry.), is sufficient and effective as against municipality of city of Edmonton, Alta., and should Peace Avenue be opened up, such opening would be subject to seniority of Ry. Co.'s title and construction.

20771—October 31—Finding and adjudging that title of Calgary and Edmonton Ry. Co., is sufficient and effective as against Mun. city of Edmonton, Alta., and that should Athabasca Avenue be opened, such opening would be subject to seniority of Ry. Co.'s title and construction.

20772—November 7—Rescinding Order No. 20624, dated October 22, 1913.

20773—November 8—Extending, until January 15th, 1914, time within which C.P.R. install bell at crossing of Port Burwell Road, at mileage 32.7 Port Burwell Branch.

20774—November 7—Authorizing C.P.R. to construct spur for loading ties from a point on southerly limit of right of way on its main line, White River Subdivision, Lake Superior Division, at mileage 44.32 from Chapleau, Tp. 43, Dist. Algoma, Ont.

20775—November 6—Authorizing C.P.R. to construct spur for Frontenac Floor and Wall Tile Co., Limited, Kingston, Ont., from a point on northerly limit of right of way, at mileage 101.58, Ont. Division, Kingston Subdivision, in Lot No. 8, Con. West of Great Cataraqua River, Tp. Kingston, Co. Frontenac, Ont.

20776—November 8—Authorizing C.P.R. to construct Lacombe Easterly Branch of Calgary and Edmonton Ry. Co., across thirty-nine (39) highways, mileage 180.61 to 221.11.

20777—November 8—Approving location C.P.R. station in Lot 16, Con. 5, Tp. Tay, Co. Simcoe, Ont., at Port McNicoll, at mileage 88.32 on Port McNicoll Subdivision, Ont. Division.

20778—November 10—Rescinding Order No. 20638, dated October 22nd, 1913.

20779—November 10—Authorizing C.P.R. to open for traffic portion of Lacombe Easterly Branch from Consort, at mileage 139, to Monitor, at mileage 149.

20780—November 8—Directing that, on or before June 1st, 1914, the C.P.R. install improved type of automatic illuminated electric bell at crossing of public road east of Mountain Grove Station, Ont., at mileage 44.65 on Havelock Subdivision, and thereafter maintain bell at its own expense; 20 per cent. of cost of installing be paid out of "The Railway Grade Crossing Fund," remainder by Ry. Co.

20781—November 10—Authorizing C.P.R. to open for traffic Lacombe Easterly Branch from Coronation to Consort, Alta., a distance of 32 miles: Provided that, pending completion of diversions, speed of eastbound trains approaching crossings at mileages 132.6 and 136.3 be reduced to 10 miles an hour, and bells be rung continuously between whistling posts and crossings. 2. Rescinding Order No. 17852, dated October 25th, 1912.

20782—November 8—Approving plan showing Logan Drain where it crosses G.T.R. in village of Blyth, Ont.

20783—November 7—Authorizing G.T.R. to construct and maintain, at its own expense, Bridge No. 62, mileage 152.25 from Black Rock, carrying 20th District of its Ry., over public road between Lot 12, Huron Road Con. and Lot 83, Maitland Con. Tp. Goderich, Co. Huron, Ontario.

20784—November 10—Approving location C.N.O.R. Parry Sound-North Bay line through Tps. Gurd, Nipissing, Himsworth and Ferris, Districts Parry Sound and Nipissing, Ont., from mileage 209.52 to 233.90, from Toronto.

20785—November 11—Approving revised location C.P.R. from mileage 5.08 to 7.16 and from mileage 9.68 to 11.51, Schreiber Subdivision, Lake Superior Division.

20786—November 11—Authorizing G.T.R. to construct siding into premises of Andrew Malcolm Furniture Co.,

Limited, town of Listowel, Co. Perth, Ont.; and to change location of existing track south of the proposed siding.

20787—November 10—Approving location C.N.O.R. Parry Sound-North Bay line through Tps. Burpee, Burton, Mackenzie, Ferrie and Mills, District Parry Sound, Ont., mileage 170 to 190 from Toronto.

20788—November 10—Approving location C.N.O.R. Parry Sound-North Bay line through Tps. Patterson, Pringle and Mills, District Parry Sound, mileage 190 to 209.52 from Toronto.

20789—November 11—Authorizing Esquimalt and Nanaimo Ry. to construct spur at Cowichan Lake, B.C., across roadway to station at that point.

20790—November 10—Directing that C.P.R. reconstruct culvert on its Chalk River Subdivision, Eastern Division, Bridge No. 53.2 near Arnprior, Ont.: work to be completed by January 1st, 1914.

20791—November 11—Relieving C.P.R. from providing further protection at crossing of public road at Cluny, Alta., at mileage 116.2 on Calgary Subdivision.

General Order No. 113—November 5—Adopting and confirming conditions and specifications set forth in Schedule hereunto annexed, under heading "Rules for Wires Crossing Railways," as conditions and specifications applicable to erection, placing or maintaining or electric lines, wires, or cables across all Rys., subject to jurisdiction of Board: Part 1 being applicable where line is carried over railway; part 2 being applicable where line is carried under Ry. 2. Any Order of Board granting leave to erect, etc., wires, lines, etc., across railway and referring to "Rules for Wires Crossing Rys.," be deemed as intended to be a reference to conditions and specifications set out in that part of said Schedule which is applicable to mode of crossing authorized. 3. Every Order granting leave to erect wires across any Ry., unless otherwise expressed, be deemed an Order for leave to erect same under and according to conditions, etc., set out in schedule applicable thereto. 4. Rescinding Order No. 8392, dated October 7th, 1909, approving "The Standard Conditions and Specifications for Wire Crossings," and conditions and specifications adopted thereby.

20792—November 11—Recommending to the Governor in Council for approval, Rules and Regulations of T.H. and B. Ry. (private instructions to train conductors).

20793—November 12—Authorizing City of Edmonton, Alta., to construct its Electric Street Ry. across G.T.P. Ry. at intersection of Twenty-Seventh Street, between Armstrong Avenue, and Cochrane Avenue, subject to certain conditions. Cost of providing half-interlocking plant be borne one-half by city and one-half by G.T.P. Ry.

20794—November 12—Directing that, within six weeks from date of this Order, G.N. Ry., fence its right of way on property of H. E. Knight of Grand Forks, B.C.; Ry. Co. to be liable to a penalty of $25 a day for every day it shall be in default of complying with provisions of this Order.

20795—November 12—Authorizing, subject to condition that traffic on highway is not obstructed, G.T.R. to reconstruct bridge carrying Durham Road between Con. 1 North and Con. 1 South, through Lot 72, Tp. Brant, Co. Bruce, Ont., over 22nd District, Middle Division of its railway, at Mile Post 125.25, near Hanover.

20796—November 11—Approving plan and specifications of drain, known as "Teillier Award Drain," to be constructed under G.T.R. in Lot 2, Lake Shore Con., Tp. Rochester, Ont.

20797—November 12—Directing that within 90 days from date of this Order, C.P.R. install improved type of automatic electric bell at crossing of first public highway east of Britannia, Tp. Nepean, Co. Carleton, Ont., at mileage 3.9 on Chalk River Subdivision, and thereafter maintain same at its own expense: 20 per cent. of cost of installation be paid out of "The Railway Grade Crossing Fund," and remainder by Railway Company.

20798—November 12—Amending Order No. 19430, dated May 10th, 1913, to provide that floor of subway be constructed of 6-inch concrete slab to extend full length of subway, one-half of cost be paid my Mun. Surrey, B.C., and one-half by Great Northern Ry.

20799—November 13—Approving location Alberta Central Ry. Co.'s Sounding Creek-Moose Jaw line from a point in Sec. 24-27-26, W. 3 M., to a point in Sec. 24-25-18, W. 3 M., being from mileage 220 east of Red Deer, to mileage 277.75 east of Red Deer, Sask. 2. Authorizing construction of said line across fifty-six (56) highways, mileage 220 to mileage 277.75.

20800—November 13—Authorizing C.P.R. to construct, subject to terms of agreement, spur into premises of Dominion Wire Rope Co., Limited, in Lot Cadastral No. 922, city and parish of Lachine, Co. Jacques-Cartier, Que.

20801—November 13—Authorizing, subject to terms and conditions contained in resolution of town of Lasalle, C.P.R. to construct spur for Montreal Light, Heat and Power Co., across St. Patrick St., and Lot Cadastral No. 1021, Parish of Lachine, Que.

20802—November 13—Authorizing C.P.R. to operate spur for Massey-Harris Co., Limited, from a point on existing spur in lane in Block 68, city of Medicine Hat, Alta., into premises of Massey-Harris Co., Lots 35 to 38.

20803—November 11—Authorizing C.N.R to construct across and divert public road between Secs. 24 and 23, Tp. 26, R. 23, W. 3 M., Alsask Southeasterly Line, Sask. Company, at its own expense, install and maintain improved type of automatic electric bell at said crossing.

20804—November 13—Authorizing, subject to an inspection by Department of Public Works for British Columbia after road is graded and gravelled its full length, V. V. & E. Ry. & Nav. Co., by means of an over-crossing, to construct across and divert Nicola-Princeton Highway, Lot 1775, Group 1, Yale Dist.

20805—November 1—Dismissing complaint and application of Edward A. Purcell, Saskatoon, Sask., alleging G.T.R. Ry. discriminates against his bus line in favor of Dunning Bus Line at Saskatoon.

20806—November 13—Refusing application of Rural Mun. of Fort Garry, Man., for Order directing C.N.R. to construct suitable crossing over its tracks across Fairfield Ave.

20807—November 13—Authorizing Director of Surveys for Alberta, to construct a diversion of road allowance in S.W. ¼ Sec. 32-18-14, W. 4 M., Alta., across C.P.R.

20808—November 13—Authorizing C.N.R. to divert Rue La Verandrye, city of St. Boniface, Man.; and take for purpose of such diversion, parts of Lots 572 and 574, D. G. S. 76 Plan 224 of said city, property of C. A. Gareau, subject to condition that company construct, as soon as new station is erected, a good 30-foot road alongside its right-of-way, from Rue La Verandrye to Rue Notre Dame, and grade said road properly leaving it in as good condition as Rue La Verandrye between Rue St. Jean Baptiste and crossing over tracks of Ry. Co.

20809—November 13—Authorizing C.N.O.R. to construct across and divert public road on Lot 38, Con. 18, Tp. Ferris, Stations 981 to 991. And rescinding Order No. 20060, Aug. 13th, 1913.

20810—November 13—Authorizing C.P.R. to construct, by means of grade crossing, its siding extension across public road at Worthington, Ont. 2. Authorizing, subject to terms of resolution, Ry. Co., to construct said sidings for Mond Nickel Co., Limited, Coniston, Ont., from a point on northerly limit of right-of-way, at Worthington, across public road and lands adjoining, in Lot 2, Con. 2, Tp. Drury, Dist Sudbury.

20811—November 13—Authorizing C.P.R. to construct extension to existing siding for Dominion Radiator Company, Toronto, Ont.

20812—November 13—Directing Municipality of North Cowichan, B.C., to move crossing of highway at mile-post 41—6½ feet from its present location to a point 1,350 feet south of mile-post 41. And rescinding Order No. 6642, February 27th, 1909.

20813—November 13—Amending Order No. 19506, dated June 7th, 1913, by substituting plan marked "A," dated September 2nd, 1913, for plan dated March 24th, 1913, approved by said Order.

Tarvia

Preserves Roads
Prevents Dust~

Lady Grey Road, Government Road, Ottawa, Ont. Canada's Mint in foreground. Parliament Buildings in background. Tarvia Modern Pavement finished Aug. 1, 1913.

A New Principle in Road Building

IT has long been recognized by engineers that one of the greatest causes of the destruction of macadam roads by traffic has been the internal movement caused by the passage of heavy loads. The endless shifting and creeping of the lower courses of stone causes a grinding and pulverization which destroys the stone and breaks the bond.

To reduce this internal movement engineers have buried the larger stone under successive layers of finer stone. This fine stone forms dust more rapidly but the dust serves to protect the foundation of the road by acting as a cushion. Modern traffic makes the use of such dust cushions quite impracticable, for the automobiles not only stir up the dust but create entirely new conditions by scouring the surface of the road and breaking the bond with the backward thrust of their driving wheels.

The possibility of making roads automobile-proof by using Tarvia as a binder from top to bottom of the wearing-course during the construction of the road has now been satisfactorily demonstrated. The Tarvia fills the voids and forms a tough, durable matrix in which the stone cannot shift or grind. Consequently it has become possible to use large stone in a much greater proportion of the construction. The fine screenings and stone chips are used only on the surface as a finishing coat.

Traffic wearing away the surface strikes the layer of large stone in the tarvia matrix and makes little or no impression upon it. The large stone pulverizes but slowly and cannot be torn loose by automobile wheels. It does not change contour, sheds water instantly, is free from dust, costs but a trifle more to build than ordinary macadam, costs much less to maintain.

RAILWAYS—STEAM AND ELECTRIC.

Brandon, Man.—One of the most important items on the business agenda at the last meeting of the Brandon board of trade, was the consideration of the action of Le Pas board of trade in preparing a petition to the Dominion Government, praying for the compulsory building of connecting railway lines with the Hudson's Bay. The Brandon board of trade passed unanimously a resolution endorsing the Le Pas petition.

Bridgeburg, Ont.—If the line projected by the C.N.R. to operate from Toronto to Buffalo, is built to Bridgeburg, it is believed that a new bridge and possibly a tunnel will have to be constructed at Fort Erie.

+—Calgary, Alta.—The contract for the temporary station to be erected right away on the C.N.R. property near the end of the line at Elbow River, was awarded to CARTER-HALLS AND ALDINGER of Winnipeg; and it will be completed within the next three weeks. The building will be frame and ironclad; and one freight shed about 500 feet long will be erected at the present time.

Calgary, Alta.—The plans for the new permanent C.N.R station to be erected on the north side of the Elbow River, are ready; and the chief bridge engineer at Calgary has received information that tenders will be called soon for the letting of contracts.

Edmonton, Alta.—The surveyors are making the preliminary survey of the route of the Alberta and Great Waterways Railway from Edmonton to Fort McMurray. W. R. Smith, chief engineer of the Edmonton, Dunvegan and B.C. line, is directing operations. The arrangements made with J. D McArthur and associates, contractors, call for the commencement of work before the end of the year. Construction will commence on a portion of the original route which is to be maintained.

Fort William, Ont.—The application of the city to the Dominion Railway Commission to compel the C.N.R. to build a station at Fort William was considered at the session of the Commission held recently at Port Arthur. Mr. Spence, a member of the staff of the Commission, was appointed to go over the situation and to report in two weeks.

Fort William, Ont.—It has been decided finally by the Fort William council that the city will operate its street railway as a separate unit, thus leaving Port Arthur to direct the section within its own limits. However, the one fare for the two cities, compulsory by legislation, will continue.

Moncton, N.B.—The I.C.R. proposal in connection with the abolition of level crossings has been discussed by city council and Board of Trade committee. The I.C.R. general manager, Mr. Gutelius, was present and several details of plan were considered. Mr. Gutelius said that the wharf track route, as advocated by some, who opposed the present plan, is out of the question. The council will meet again to deal with the matter.

Montreal, Que.—In connection with the improvement of the Grand Trunk terminals at Montreal, city engineers have furnished estimates for elevating the tracks from Bonaventure Station to Point St. Charles, which approximate $5,500,000. It has also been made known that the widening of the old Wellington subway is a part of the city's programme.

Ottawa, Ont.—A charter will be sought at the next session of Parliament by the Ontario Lake Front Terminal Railway, which proposes to build a line from a point on the C.P.R. between Havelock and Central Ontario Junction, to Cobourg, by way of Campellford, and from the latter town to Brighton.

Ottawa, Ont.—Application will be made at the next session of parliament for an act to incorporate the Pacific, Peace River and Athabasca Railway Company, Limited. The company desire power to construct a line of railway which will total about 1,500 miles.

Owen Sound, Ont.—At the last meeting of the Owen Sound council, it was decided to request the Ontario Hydro-Commission to furnish estimates on a Guelph to Owen Sound radial line. A committee, consisting of Mayor Lemon, Ald. McQuaker and Town Clerk Gordon was appointed to deal with any details in connection with the project.

Port Arthur, Ont.—Concerning the application of the C.N.R. to build a spur line from its line of railway along Hester Street, Port Arthur to Fort Street, and to cross several of the city's streets and also the electric street railway on Algoma Street, the Dominion Railway Commission decided that an order would take effect when satisfactory arrangements were made by the interested parties.

St. Catharines, Ont.—A by-law to bonus the C.N.R. to deviate its route to run through St. Catharines, is to be submitted to municipal ratepayers in January, 1914.

Toronto, Ont.—The city council has decided to have an agreement prepared covering the proposed street railway deal; and if this is not ready in time to submit to the people as a by-law on January 1st, to have a synopsis covering the situation prepared and submitted on that day as a plebiscite.

Vancouver, B.C.—Mr. J. J. Hill of the Great Northern Railway has stated that there is not the slightest probability of the railway from Vancouver to the Yukon being built with money supplied by the Standard Oil Company.

Vancouver, B.C.—A shorter route for the Kettle Valley Railway from Okanagan to Mitchell has been planned and filed with the authorities at Ottawa. The proposed line will run from Coldwater Summit to Osprey Lake, near the headquarters of Deep Creek, which flows into Okanagan Lake near Peachland. The construction of a line from Peachland to Osprey Lake would save a long detour and open up a stretch of new territory north of Hope Mountain road. The route of the Kettle Valley Railway as mapped out originally, merely skirted the shores of the lower end of Okanagan Lake on the west side, branching from Penticton in a northwesterly direction and following the course of Five-Mile Creek to Tulameen. Under a recent arrangement the railway will go further north than in the earlier plans and will serve Summerland.

Victoria, B.C.—The British Columbia Electric Railway are calling for tenders for the construction of an interlocking tower at the Esquimalt and Nanaimo railway crossing on the Esquimalt road, near Russell station.

Winnipeg, Man.—The South Fort Rouge ratepayers are requesting the city council to urge the matter of electrification of the C.N.R. cut off in Winnipeg.

GARBAGE, SEWAGE AND WATER.

Edmonton, Alta.—Superintendent Parsons, of the water power station, has written to the city commissioners to advocate the adoption and installation of water meters throughout the city in order to check waste and to put all consumers on an equal footing.

Galt, Ont.—The water commission has decided that a greater storage capacity is required at the pumping station, and will build a new reservoir. The present storage supply is 150,000 gallons, and it is planned to increase this to 800,000 gallons. The present intention is to let the board of works undertake the excavating, so that the stone taken out may be used for road purposes.

Hamilton, Ont.—Contracts have been awarded THE SMART-TURNER MACHINE COMPANY by the National Builders' Supply and Concrete Brick Company, Quebec, for the supply of one duplex pump; by Messrs. H. D. Smith and Company, Winona, Ont., for one duplex pump; by the Hamilton Bridge Works, for a duplex power pump; by the St. Lawrence Paper Mills, Thorold, for one centrifugal pump; by W. A. Freeman Company, Limited, Hamilton, for one duplex pump; by the Gananoque Electric Light and Water Supply Company, for one centrifugal pump; by the Lotbiniere and Megantic Railway Company, Lystar, Que., for one duplex pump; and by the London Cold Storage and Warehouse Company, for one duplex pump.

Hamilton, Ont.—Tenders will be received up till November 20th for the construction of pipe sewers on several portions of streets. Plans and specifications may be obtained from the office of the City Engineer. Signed, S. H. Kent, Esq., City Clerk, Hamilton.

Kamloops, B.C.—The water board meeting now at Kamloops, and afterwards at Ashcroft, has in consideration many difficult problems concerning the water solution for the interior district of British Columbia. Some claims for records for four times more water than is available in the best of seasons date back to 1865, and many are involved with litigation.

Ottawa, Ont.—It is understood that tenders will be called for immediately for the connection of a sewer system through the C.P.R. yards to the river.

Port Arthur, Ont.—1,400 feet of the city intake pipe must now be repaired owing to the tearing out of the entire section by the steamer G. R. Crowe, when entering the drydock on November 12th.

Stanbridge East, Que.—A project is in hand to build a waterworks system from Selby Lake to supply Dunham, Frelighsburg, Stanbridge East and Bedford. It will be submitted to each municipality for consideration.

Toronto, Ont.—In his report to the Committee on Works, Commissioner Harris discourages the proposal to supply city water to a subdivision, 1,360 feet beyond the municipality, in view of the 500 foot limit set by the city council.

Vancouver, B.C.—The Burrard Peninsula Joint Sewerage Commission has decided to call for tenders for the southern extensions of the China Creek trunk sewer on China and Canoe creeks. The tenders are to be in the hands of the commission by December 1st. As much of the work as is possible will be completed this winter.

Victoria, B.C.—The Esquimalt Municipal Council has approved the draft agreement with the city in regard to the main trunk sewer, which has been previously carefully considered in committee; and the Reeve was authorized to sign it.

Victoria, B.C.—The Oak Bay ratepayers voted on November 15th upon a by-law to borrow $150,000 for sewer purposes, and another for $35,000 for the laying of water mains. The work proposed, if carried out, will provide water and sewer connection for every subdivided lot in the municipality.

Victoria, B.C.—Decision in connection with the award of contract for concrete flow line on the Sooke Lake waterworks system has once again been deferred for a special meeting of council when it is expected Mr. Wynn Meredith will be present. The answers of the Graff Construction Company to questions put by Water Commissioner Rust have been forwarded by the company to the individual members of the council; but these are to be considered further by the members before the special meeting will be called. Mr. Rust's report in connection with the qualifications, financial and otherwise, submitted by the Graff Construction Company, reiterates the recommendation, which he and Mr. Meredith, the city's consulting engineer on the Sooke work, have made on previous occasions,—e.g., that, after due consideration of the company's representations, he cannot recommend that its bid be accepted; but rather that the city council should award the contract to the next lowest bidders, the Pacific Lock Joint Pipe Company.

Victoria, B.C.—Tenders will be received up till November 24th, 1913, for the fabrication and laying of 10¼ miles of 36-inch rivetted steel pipe, etc., on the Sooke water supply pressure conduit. Plans and specifications may be obtained from C. H. Rust, Water Commissioner, Victoria, B.C.

Victoria, B.C.—The city council has voted $8,000 to repair the damage occasioned through the collapse of the large brick sewer on Oxford Street, between Moss Street and Linden Avenue; but an investigation of the break has made it certain that the same causes which resulted in the cave-in on that section of the street prevail on other portions and also around on to the adjoining streets. The pavement shows signs of sagging in a number of places, indicating that the sinking of the soft bed on which the sewer was constructed is progressing, and it is only a question of a short time until a greater section of the sewer collapses and the pavement above subsides. It is predicted that to make a proper repair of the weak portion of the sewer work and replace the pavement will cost somewhere in the neighborhood of $30,000 or $40,000.

LIGHT, HEAT AND POWER.

Brantford, Ont.—Residents of Parkdale, Grandview and vicinity, Echo Place and Paris Hill have petitioned the Provincial Hydro-Electric Commission for service when the power shall have reached Brantford.

Brockville, Ont.—Tenders will be received for the supply of two 300 H.P. water tube boilers, and for an electric-driven turbine pump. Plans and specifications may be obtained from the Brockville Water and Light Department. E. J. Philip, manager.

Edmonton, Alta.—Before this city will enter into an agreement for the supply of gas, other cities will be asked to supply Edmonton commissioners and public works committee with copies of the agreements entered into by them, in order to serve as a guide to the committee for Edmonton in drafting an agreement or franchise.

Fredericton, N.B.—The Provincial Government will be requested by the city council to have the fence at the Provincial Normal School provided with lights similar to those around the Military Depot, installed by the Dominion Government.

+—**Guelph, Ont.**—The contracts have been awarded by the Public Works Department to STEVENSON & MALCOLM COMPANY for plumbing, heating, ventilation, and wiring of the following new O.A.C. buildings; the husbandry building, at a cost of $13,783; the poultry building, at $8,375; the dining hall, at $11,781.

+—**Hamilton, Ont.**—The contract has been awarded the HAMILTON STANDARD UNDERGROUND CABLE COMPANY, for the cable on the Hydro system, at a cost of $53,674.85.

London, England.—It was announced last night that the Postmaster-General is prepared to consider applications for the construction of the second of the three high-power wireless stations of the Imperial chain. Bids may be made by any wireless company, syndicate, or firm of contractors who are able, by means of a practical demonstration, to satisfy the Postmaster-General of the efficiency of their system.

London, Ont.—Negotiations between the street railway and the Ontario Power Commission for the purchase of power have been completed: a contract has been sent to President H. E. Everett of the road at Cleveland, and, when returned to the city water commission, will be turned over to the local department.

London, Ont.—President Everett of the London Street Railway Company has returned, signed, the contract between the city and the railway company for the supply of hydro-electric power for the operation of the Sunday street railway system. The contract calls for $36 a horsepower for direct current and the company may pay a flat rate or a ready-to-serve service with a meter charge.

London, Ont.—Tenders have been called for the transforming machinery that will be necessary to convert hydro power into direct current for the street railway. The day fixed for the delivery of the power is now February 15th, instead of December 15th, as originally intended.

Moncton, N.B.—Among other matters discussed at the last meeting of the city council, was the lighting question, and general dissatisfaction was expressed about the service the city was getting from the Tramways Company, and a committee was appointed to look into the proposition of installing an electric plant at the new pumping station to supply the streets, pumps, and civic buildings with electricity.

Nelson, B.C.—By a large majority a money by-law was passed in Nelson by the property owners to purchase for $50,000 the Nelson Coke and Gas Company's plant. Nelson now owns the municipal power plant, waterworks, gas, street-making plant and is negotiating for the street railway system.

Ottawa, Ont.—Tenders will be received up till November 21st, 1913, for heating, plumbing and electric wiring for the Registry Office, Haileybury, Ont. Plans and specifications may be obtained from the Department of Public Works, Ottawa. H. F. McNaughten, Secretary.

Regina, Sask.—Mr. T. A. McNulty and Mr. Eugene Cost, president of the Canadian West Natural Gas Company, have submitted to the city a proposal to supply Regina with gas at a figure for large users of about 25 cents per 1,000 feet, and for domestic use of about 40 cents. Regina citizens will vote upon the proposal within a few weeks.

+—**Toronto, Ont.**—The Abitibi Pulp and Paper Company has placed an order with the CANADIAN ALLIS-CHALMERS COMPANY, LIMITED, for two high-lift turbine pumps for ground wood stock, each 4,000 U.S. gals. per min., against 116 feet head 200 b.h.p.; two high-lift turbine pumps for grinder pressure supply, each 450 U.S. gals. per min., 231 feet head 40 b.h.p.; and one high-lift turbine pump for mill water supply 4,000 U.S. gals. per min., 173 feet 250 b.h.p. There will also be two 14-inch centrifugal pumps for white water supply each 4,000 U.S. gals per min., 35 feet head and 75 b.h.p., and two 4-inch centrifugal pumps for slivers each 500 U.S. gals. per min., 20 feet head and 8 b.h.p. All these pumps will be driven by Canadian General Electric motors.

Vancouver, B.C.—It is planned to build at Vancouver a municipal electric lighting and power plant at a cost of $300,000. Current is to be generated by turbine engines driven with steam generated in oil burning furnaces. In addition, a gas plant is being considered.

Winnipeg, Man.—Tenders will be received up till November 25th for the manufacture and delivery of a quantity of waterproof insulated copper wire. Plans and specifications may be obtained from the office of the Light and Power Department, 54 King Street, Winnipeg, Man. Signed, M. Peterson, Esq., Board of Control, Winnipeg.

Winnipeg, Man.—Tenders will be received up till November 21st for the supply and delivery of one 500 k.w. motor generator set for the King Street sub-station. Plans and specifications may be obtained from the office of the City Light and Power Department, 54 King Street, Winnipeg, Man. M. Peterson, Esq., Secretary, Board of Control, Winnipeg.

BRIDGES, ROADS AND PAVEMENTS.

Calgary, Alta.—A petition from the people of East Calgary, asking that a new bridge be constructed across the Canadian Pacific Railway Company's irrigation canal at Seventeenth Avenue East, at the city limits, and that the road there be straightened out, has been received by the city commissioners, and will be given consideration by them.

Calgary, Alta.—The city council has passed the by-law calling for the paying by the city of half of the expense of the grading of Mission Hill, done by F. C. Lowes and Company.

Edmonton, Alta.—The Provincial Government is contemplating the construction of a bridge across Saskatchewan Avenue from Eighth Street to the Parliament buildings; and it is asking concessions from the city regarding overhead crossings on the avenue.

Edmonton, Alta.—The steel for the Fifth Street low-level bridge will arrive in Edmonton this month and in the beginning of December; and the erection crew will carry out the work according to contract. The government is loaning its plant, the city paying for repairs and maintenance while the machinery is in its employ.

Fort William, Ont.—A committee of six is to be chosen to lay out a propaganda for road building in the vicinity of Fort William next year. The city council recommended that two members of the board of trade, two from the real estate exchange, and two from the city council, be appointed to form this committee.

Hamilton, Ont.—The residents of Maple Avenue have raised money by private subscriptions to build a permanent road, the county to assist by paying two-thirds of the cost. Work has been commenced under the supervision of J. G. Wilson, County Superintendent.

Kingston, Ont.—Tenders will be received up till November 24th, 1913, for the construction of Dog Lake Bridge in the 11th concession of the township of Storrington, County of Frontenac. Plans and specifications may be obtained from the offices of the County Clerk and Consulting Engineer. Signed, G. C. Wright, C.E., Consulting Engineer, Kingston; J. W. Bradshaw, County Clerk, Court House, Kingston, Ont.

Minnedosa, Man.—Speaking at a public meeting in Minnedosa on November 7th, Sir Rodmond P. Roblin, Premier of Manitoba, announced that at the next session of the legislature a bill will be introduced authorizing the expenditure on a capital account of $2,500,000 for the purpose of improving the rural highways.

Toronto, Ont.—A report has been extended by Commissioner Harris to the Committee on Works, announcing the extension of Wilton Avenue from Yonge Street to the Kingston Road in course of a year or two. The Commissioner has also recommended the widening of Clara Avenue to 66 feet and its extension to Clendenan Avenue at a cost of $13,250.

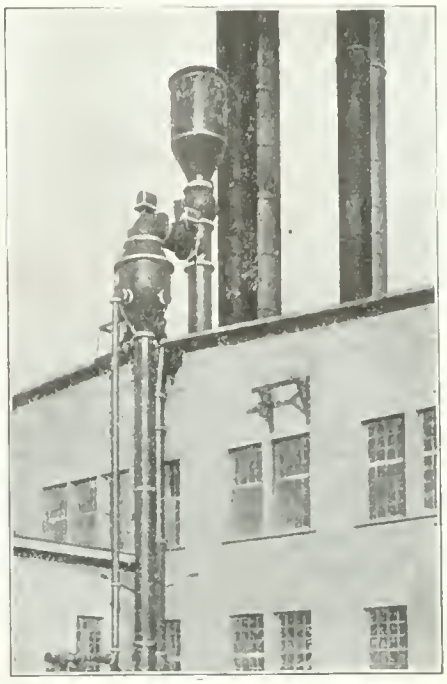
Toronto, Ont.—The council of the Municipal Corporation has given notice that improvement works to sidewalks, pavements, curbing and sewers, will be constructed on portions of several of the local streets, and that it is intended to specially assess a part of the cost upon the land abutting directly on the said streets.

+—**Vancouver, B.C.**—The contract has been awarded MESSRS. ARMSTRONG MORRISON AND COMPANY of Vancouver for the building of substructure for the Kettle Valley Bridge, which will span the Fraser River at Hope. The structure will be 1,000 feet long and the estimated cost between $575,000 and $1,000,000.

CONDENSING APPARATUS

specially designed to secure

GREATER STEAM ECONOMY



WORKS: WILLIAM and SEIGNEURS STREETS, MONTREAL

THE JOHN McDOUGALL CALEDONIAN IRON WORKS CO., Limited

Manufacturers of Boilers, Castings, Condensers, Elevators, Engines, Filters, Forgings, Hydraulic Machinery, Pumps, centrifugal and reciprocating, Steam Turbines, Tanks, Water Wheels, Water Works Plants.

Sewage Disposal

is best accomplished by means of

THE HAMPTON SEDIMENTATION TANK

This tank is not an experiment. It has been used at Norwich, England, for a number of years with most satisfactory results and has *proved* its efficiency and economy.

Used in connection with an electrolytic hypochlorite treatment, the process would be *absolutely odorless and the affluent free from disease germs.*

If you would like facts and figures write to

Sterilization Company

9-15 CLINTON ST., NEWARK, N.J.

A Perfect Weir Gage

Carries an unusually large card and will register without any reduction through a variation of two feet or on a two to one reduction through a variation of four feet.

Can be applied anywhere where fluctuation is within limit named and where great accuracy is desired.

In use on weirs, sewage disposal plants, irrigation and stream gaging.

INDUSTRIAL WORKS.

Marshville, Ont.—Tenders will be received up till November 27th, 1913, for the repair of Biederman drain in the townships of Wainfleet and Humberstone. Plans and specifications may be obtained from Reeve P. J. Willson, Forks Road, Wainfleet. Address, Marsnville P.O., Ont.

Montreal, Que.—Hon. Robert Rogers has confirmed the report that a large drydock will be erected in Halifax harbor, though he is unable to say whether the location will be on the Halifax or on the Dartmouth side until the matter has been decided by competent engineers. The work, however, is to be commenced almost immediately.

Ottawa, Ont.—Tenders will be received up till December 15th for the renewal of south pier at Burlington Channel, Ont. Plans and specifications may be obtained from the Department of Public Works, Ottawa R. C. Desrochers, Secretary.

Sault Ste. Marie, Ont.—The by-law, voted upon on November 17th, to grant a bonus of $20,000 a year, for 20 years, to the newly-organized Lake Superior Drydock and Shipbuilding Company, has been passed almost unanimously. The work will be commenced not later than April 1st, 1914.

Vancouver, B.C.—Mr. H. H. Stevens, M.P., for Vancouver, has had an interview with the Hon. Samuel Hughes in regard to the Vancouver Coal Harbor plans. Mr. Stevens urged that the causeway and ground plans be approved with as little delay as possible, and is satisfied that the minister will take early action in the matter.

MISCELLANEOUS.

New Westminster, B.C.—The city council has passed a by-law giving the Heaps Engineering Company a year's extension of time to fulfil the terms of their contract with the city for the lease of property on Lulu Island, under which they had to have a building, plant and stock in trade thereon to the value of $150,000 within a year of the signing of the lease. The company has so far expended $37,531 on their developments there and explained that had it not been for the world-wide money stringency would have been able to complete their contract.

+—Ottawa, Ont.—The contract has been awarded the POLSON IRON WORKS, of Toronto, by the Dominion Government for engines to be installed in the Lady-of-the-Lake, being built at Sorel. The cost of the engines will be $17,250.

+—Ottawa, Ont.—The contract has been awarded W. H. McGILLIVRAY, of Ottawa, by the Dominion Government for the construction of a building for Geodetic survey adjoining the Dominion Observatory, at a cost of $61,948.

Ottawa, Ont.—Tenders will be received on December 1st, December 3rd, and December 15th, respectively, for certain stores to be delivered at H. M. C. Dockyards at Halifax, N.S., and Esquimalt, B.C. Plans and specifications may be obtained from the Department of Public Service, Ottawa, Ont. C. J. Desbarats, Deputy-Minister.

Ottawa, Ont.—Mr. John Coates of London, England., in his report given by Controller Hinchey, recommends strongly the construction of a municipal gas plant at an estimated cost of $318,000 for the first unit. It is probable that the proposal will be voted upon in January. Whereas the city is practically paying $1.53 per thousand to the Ottawa Gas Company, the report shows that the city can supply gas at 85 cents per thousand.

Ottawa, Ont.—Tenders will soon be called by the Department of Marine and Fisheries for the largest and most modernly equipped ice-breaker that has yet been put into commission. It is to be used exclusively for the St. Lawrence route, and the conditions for the awarding of contract call for the building of the vessel in Canada.

▲—Toronto, Ont.—Tenders will be received up till December 2nd, 1913, for crushed limestone, cedar posts, Portland cement, etc. Plans and specifications may be obtained from Room 12, Department of Public Works, City Hall, Toronto, Ont. H. C. Hocken (Mayor), Chairman, Board of Control.

Trail, B.C.—A force of structural steel workers from Vancouver will be engaged for some time erecting steel for the new lead furnace building and for the installation of two large electric cranes. The work will be under the supervision of R. Tench, of the firm of Tench and Company, Vancouver.

Vancouver, B.C.—The civic board of work has sanctioned the proposed overhead new long-distance circuit of the British Columbia Telephone Company.

Vancouver, B.C.—Plans are under way at Vancouver to construct a big furnace for the manufacture of pig iron. The company, it is said, will have a capital of $15,000,000.

+—Victoria, B.C.—The contract has been awarded to the ERIE BASIN DRYDOCK COMPANY, of New York, by the Alaska Pacific Steamship Company for alterations to the newly-acquired steamers Admiral Dewey and Admiral Schley. The work consists of the installation of fuel oil-burning systems, winches, and other cargo-handling equipment, and the rebuilding of the interior of the vessels. The work will cost approximately $200,000, and is to be completed in 60 days.

Victoria, B.C.—Tenders will be received up till November 24th, 1913, for the construction and erection of metallic circuit telephone line of two wires, etc. Plans and specifications may be obtained from C. H. Rust, Water Commissioner, Victoria, B.C.

+—Winnipeg, Man.—The contract has been awarded the NEW YORK FOUNDATION COMPANY by the C.P.R. company for the straightening of the North Transcona elevator. Owing to the almost unprecedented nature of the undertaking, it is not known exactly how long the work will take.

Winnipeg, Man.—Tenders will be received up till December 15th for the supply of two 60 h.p. motor hose wagons, and one 75 h.p. motor aerial ladder truck. Plans and specfications may be obtained from the office of the Chief of the Fire Department, Central Fire Station, Winnipeg, Man. Signed, M. Peterson, Esq., Secretary, Board of Control, Winnipeg.

Winnipeg, Man.—The Winnipeg centre of the Royal Astronomical Society has instructed its secretary to write to Dr. King, head of the Dominion observatory at Ottawa, and to urge upon him the advantages of having the new telescope, ordered for Canada, located at Winnipeg.

CURRENT NEWS.

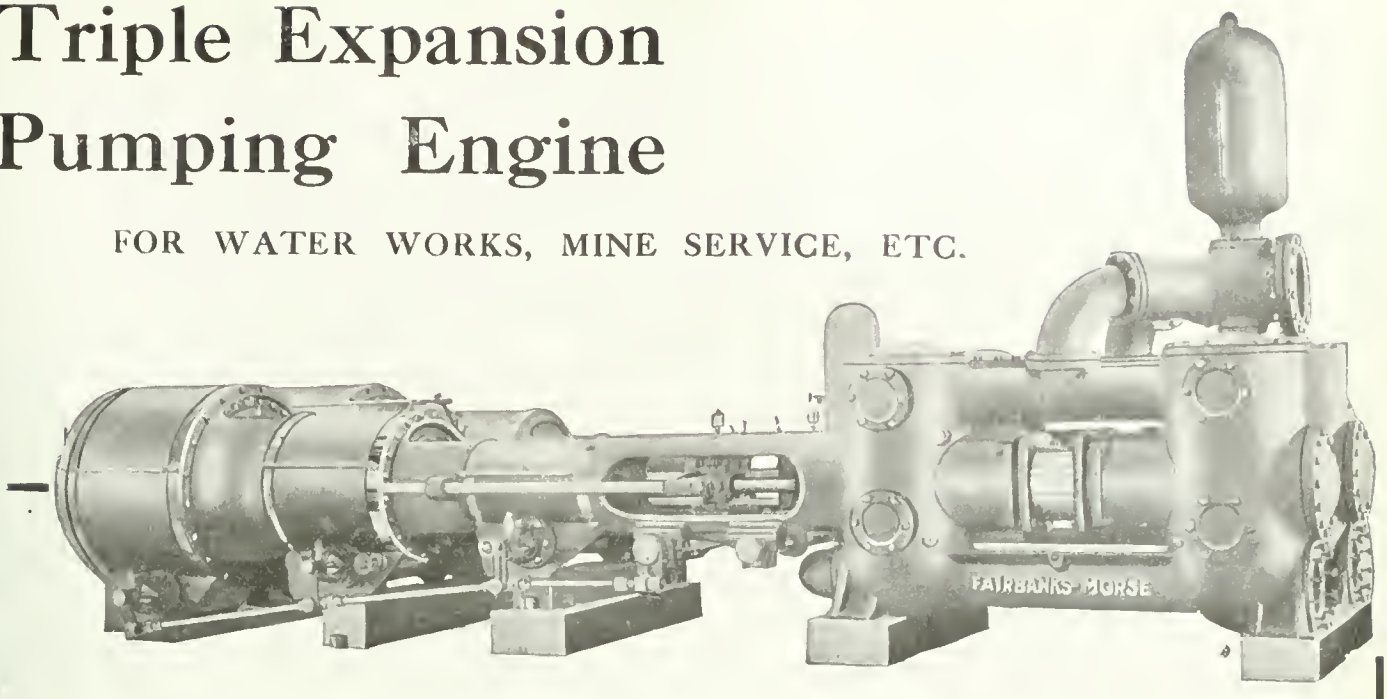
Calgary, Alta.—Mr. M. M. Biederman, superintendent of bridge construction for Frankman Brothers, of Winnipeg, the contractors, has stated that the bridge work on the C.N.R. line into Calgary will be completed within 40 days. Biederman has a crew of some 20 bridge workers and rapid progress is already being made on the bridge across the Canadian Pacific Railway tracks. It is thought that early next week the traveling crane will be able to run across it and begin work on the Bow River bridge. Owing to the fact that two girders were seriously damaged in a wreck last week, they will have to be returned to the manufacturer for repairs, which may slightly delay the work on the Bow River bridge. The two smaller structures are relatively unimportant and can be spanned, if necessary, by false-work and timber trestling sufficiently strong for general purposes.

Cornwall, Ont.—The St. Lawrence River Power Company's dredge "Zangle," which is to be used in dredging the Grasse River from Massena to the point where it enters the St. Lawrence, a distance of 7 miles, is in the drydock at Cornwall. A large steel box is being removed from beneath the dredge, so that less difficulty will be experienced in navigating the Grasse River to Massena to commence operations. It is expected that a start will be made upon the work this season, and that it will take about three years to complete the widening and deepening of the Grasse River so as to make it possible for the St Lawrence River steamers to navigate its waters and make a port at Massena.

Edmonton, Alta.—The concrete work is now finished on the bridge over the C.P.R. tracks at the south end of the high level bridge; and soon the entire structure will be complete.

Triple Expansion Pumping Engine

FOR WATER WORKS, MINE SERVICE, ETC.



The Fairbanks-Morse Triple Expansion Duplex Outside Centre Packed Plunger Pumping Engine shown here is very economical in the consumption of steam. The economy of operation makes this Pump preferable to all others in many situations.

The steam end is fitted with semi-rotative valves. The plungers being externally packed are always in sight and any leakage can be at once detected. All parts are easy of access. The stuffing boxes are large and deep, so that ample allowance of packing may be used.

This type of pump is heavily proportioned throughout in order to meet the demands of heavy service. It is designed to give long and satisfactory service at a minimum cost. It has a 24-inch stroke and a capacity of 2,500,000 gallons per 24 hours.

Departmentalising a Great Business

The marketing of one article is a very simple problem. As the number and variety of the products you sell increase, the complexity of your merchandising problem grows.

Our business has grown in the last dozen years from a comparatively few products into an enormous number of lines. This tremendous growth has necessitated the organizing of our business along departmental lines with able, efficient men at the heads of the various departments.

As organized now we can serve the mechanical field better than any house in Canada. In addition to being manufacturers, we are literally a large "departmental house for machinery and mechanical goods." This bringing together of a vast number of lines and classifying them according to departments is the kind of combination in industry that makes for efficiency, economy and better service.

It is just as great a convenience to Engineers, Contractors and Builders to be able to get their supplies from one House as it is to the general public to shop in a large, modern department store. In dealing with us you can get what you want "under one roof." Write, phone or call.

The Canadian Fairbanks-Morse Co., Limited

"The Departmental House for Mechanical Goods"

Fredericton, N.B.—By January 1st, the Dominion Government's Experimental Station a few miles below this city will have a pneumatic water supply plant, which is now being installed and will be completed by the end of this month. The water will be pumped from the well which was bored at the Experimental Farm this summer by Mr. Thomas Kent, of St. George. Superintendent W. W. Hubbard has had two tests made of the water by S. T. Shutt, the Dominion Government's chemist, at Ottawa, and they have shown the water to be of the very best quality. The tank is 26 feet long and 7 feet in diameter, with capacity of 7,000 gallons. It is estimated that 5,000 gallons per day will be required and this can be obtained by the pump working two hours a day. One twenty-four hour test has been made and 26,000 gallons were obtained in that time, and the water-level lowered only two feet in the tank.

Grandview, Sask.—One of the government elevators has been burned to the ground, including a loss of the entire elevator capacity of 30,000 bushels of wheat.

Grenfell, Sask.—On Monday, November 10th, the municipal electric light plant was put into commission, and is running with great satisfaction.

Guelph, Ont. City Engineer Holland has decided that the Neeve Street bridge shall not be opened to street car traffic for at least two weeks. Only three of the 13 beams are built on a solid earth base, and the cement should be allowed ample time to ripen, he claims, before traffic passes over it.

Hamilton, Ont.—Favorable progress is reported on the work of repairing the incline railway; and repairs have been completed in the engine house.

London, Ont.—The second track of the C.P.R. will not likely reach London before 1915. The company is now operating the double track between West Toronto and Erindale, and work is going ahead in a satisfactory manner as far as Guelph Junction. Tracks have been laid but the new roadbed is yet to be ballasted. Next year an attempt will be made to finish the line as far as Galt. Owing to the rocky nature of the country and severe natural difficulties, in the way of rock cuts and deep gullies, it is not thought that it will be possible to proceed much further in the entire season. Eventually the work will be brought on toward Woodstock and London.

Medicine Hat, Alta.—The laying of the Ansley spur, for which McCoy and Levine are contractors for the engineering work, is under way. The material is already on the ground

North Battleford, Sask.—A second extension of the C.N.R. has been commenced to run from North Battleford to Edam, the present terminus. The road is already graded from Edam to a point four miles northwest of Mervin, and it is expected the line will be constructed to Emmaville this fall. The other branch line construction from North Battleford to Blaine Lake on the east will be opened for through traffic within the next few days.

Ottawa, Ont.—It has been announced here that the substructure of the Quebec bridge has been completed save for the pointing of a couple of piers, and the erection of steel on the north shore has been commenced. This will necessitate the use of an immense "traveller" standing 300 feet over the rails and costing about half a million dollars.

Quebec, Que.—Mr. A. Leofred, president of the Aqueducts, Limited, of Quebec, states that there are more engineering projects under way at present in Quebec than has ever been the case. Recently, Mr. Leofred's company completed the construction of the Chaudiere curve at the south entrance to the Quebec bridge, which secures 5,000 h.p. water-power from the Chaudiere Falls. From this source the Quebec Electric Railway will receive power, and the railways will be supplied with water.

Regina, Sask.—On November 10th the Grand Trunk Pacific Railway opened to traffic its Regina boundary branch line between Regina and Northgate, Sask., a distance of 155 miles.

Regina, Sask.—The C.N.R. bridge across the Moose Jaw River at Main Street, has been completed, and steel is being laid.

Saskatoon, Sask.—The power rate for Saskatoon has shown a decrease for the month of October. The figure is 1.95 per kilowatt, while for September it was 2.07. There is every chance that another drop in cost of power production will occur in November; and it is hoped that the rate of from 1.46 per kilowatt to 1.71 per kilowatt per hour, prophesied some time ago by the city commissioners, will be reached in the near future.

Saskatoon, Sask.—It is announced that 50 miles of new line is soon to be opened on the Goose Lake division of the C.N.R. line, and indications are that in the spring of 1914 a more extensive program of extension work will be carried out by the company in and around Saskatoon.

Saskatoon, Sask.—The street car service commenced operating between Saskatoon and Sutherland, the C.P.R. town three and-a-half miles north-east of the city. The route of the new line is east along Eight Street, then north to Sutherland.

Smith's Falls, Ont.—The Smith's Falls Electric Power Company has completed extensive improvements to its plant at Sey's Rapids. A Westinghouse lighting machine, made in Pittsburg, capable of developing 365 horsepower and weighing over 10 tons, has been installed. It is to carry all the incandescent lights the company has or will have for some years, and will be operated by water power from the rapids.

St. Catharines, Ont.—The firm of Baldry, Yerburgh, and Hutchinson, contractors for section 2, Welland ship canal, are having 25 boilers brought from England in connection with its plant.

St. John, N.B.—At a special meeting of the St. John city council, the mayor announced that the board of trade would have a conference with the Minister of Public Works and the Minister of Marine and Fisheries and present several resolutions to them calling for the construction of 8 or 10 additional berths, the closing of the western entrance to the harbor, the building of a breakwater on the eastern end of Partridge Island, and other improvements.

St. John, N.B.—The council are considering the advisability of suggesting to the Federal Ministers that the services of an expert of international reputation be called upon to give an authoritative opinion on the present plans for developing the St. John harbor.

St. John, N.B.—Prominent C.P.R. officials have visited St. John and have inspected the local terminal facilities. Mr. Price, assistant general manager, stated that the arrangements at Halifax had been found satisfactory, and it is expected that the Empress steamers can be handled there this winter without much difficulty.

St. John, N.B.—Concerning the work on the St. John harbor improvements, the contractor, Mr. Norton Griffiths, of Ottawa, has stated that the work will be completed before the contract time, which is 1917.

The Pas, Man.—Mr. A. H. Detredeau, chairman of the board of trade, has been informed recently by Superintendent Franklin of the McArthur Contracting Company that he expects to lay steel as far as Setting Lake at mile 130 this fall. Ties are now being delivered from Edmonton and Rainy River; and work has commenced on the pier work at the Narrows bridge at mile 40. This winter, moreover, the contractors expect to build the abutments for the cantilever bridge at Manitou Rapids, which lies half way to Hudson Bay.

Thorold, Ont.—Operations on the lower extremity of No. 3 section of Welland ship canal have commenced.

Toronto, Ont.—C.P.R. officials have announced that the new south shore line of the company from Toronto to Glen Tay will be ready for the operation of a freight service before Christmas.

Vancouver, B.C.—Construction is in progress on a temporary retaining wall across False Creek, at the Main Street bridge, in connection with the reclamation work for the Canadian Northern Pacific Railway. The barrier is being built of rip-rap filled with loose rock. This is taken as a sign that the Canadian Northern Railway is endeavoring to rush along its terminal scheme. In the portion of False Creek to be used by the company for its terminals, filling-in has been proceeding for several months; and 500,000 cubic yards of material have been deposited.

Vancouver, B.C.—Some of the members of the Greater Vancouver Sewerage Board toured the Burnaby municipality and inspected prospective routes of sewers. Still Creek and Brunette River will be deepened so as to carry off surface water. Estimates of next year's work are to be prepared early, so that an early start may be made in the spring of next year.

Insuring Pumps

against their destruction by fire requires engineering knowledge that is not needed in insuring dwellings, stores, etc. We used the word "Pumps" only as an illustration. It requires sound engineering and expert insurance knowledge—combined in the one firm—to secure for any industrial or engineering firm the lowest possible insurance rates. Only a firm like ours—employing a staff of engineers—could appreciate your requirements—not only in fire insurance but also in special forms of insurance.

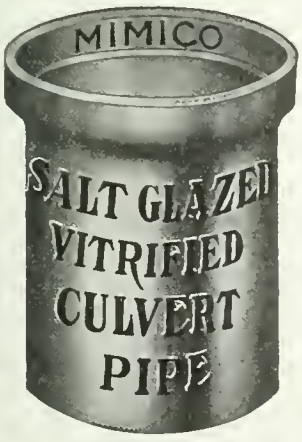
136 St. James Street - Montreal

Cost of pipe = 20% cost of work
Saving by using poor pipe = 20%
Saving on total cost = 4%

IS IT WORTH WHILE?



If the sewer is to cost $10,000, for instance, MIMICO pipe would likely not cost more than $2,000, probably considerably less. Not more than $400 could be saved on this pipe cost by purchasing a poor grade of pipe. You would then have a poor sewer costing $9,600, when for $10,000 you might have had the very best sewer possible to build. Is it worth while to buy poor pipe? No! Then buy Mimico Brand and put an end to sewer troubles.

Prices on request.

Practical Methods of Sewage Disposal.

For Residences, Hotels and Institutions.
By HENRY N. OGDEN, Mem. Amer. Soc. C.E., Professor of Sanitary Engineering, Cornell University, and H. BURDETT CLEVELAND, Assoc. Mem. Amer. Soc. C.E., Principal Assistant Engineer, New York State Department of Health.
8vo, vi. 132 pages, 52 figures. Cloth, $1.50 net.
Contains tables for use in constructing the different types of plants together with the necessary plans, sections, views, etc.

IN THREE VOLUMES

Applied Mechanics.

By CHARLES E. FULLER, Professor of Theoretical and Applied Mechanics at the Massachusetts Institute of Technology, and WILLIAM A. JOHNSTON, Professor of Theoretical and Applied Mechanics at the Massachusetts Institute of Technology.

VOLUME I. STATICS AND KINETICS.
8vo, xi. 379 pages, 212 figures. Cloth, $2.50 net.
A large number of problems, some simple others more complex, illustrating the application of the principles discussed in the text have been included and solutions have been given when it was deemed necessary to indicate the methods of applying the principles. It is the experience of the authors, that the student's power to clearly grasp the subject comes to a large extent, from his efforts to solve original problems.

VOLUME II. STRENGTH OF MATERIALS (in Preparation).

VOLUME III. GRAPHIC STATICS (in Preparation).

PUBLISHED RECENTLY

Logging.

The Principles and General Methods of Operation in the United States.
By RALPH CLEMENT BRYANT, F.F., M.A., Manufacturers' Association Professor of Lumbering, Yale University.
8vo, xviii. 590 pages, 133 figures. Cloth, $3.50 net.
The more important features of operation are covered in this book. Discusses at length the chief facilities and methods for the movement of timber from the stump to the manufacturing plant, especially logging railroads.
The greatest emphasis is laid on features about which there is not much written material available.

The Theory and Practice of Working Plans (Forest Organization).

By A. B. RECKNAGEL, B.A., M.F., Professor of Forestry, Cornell University.
8vo, x. 230 pages, illustrated. Cloth, $2.00 net.
Designed both for the student and the practicing forester. In preparing this book the author constantly kept in mind the experience which he gained while doing active work for the Forest Service in various parts of the United States.

Vancouver, B.C.—On his return to-day from London, Sir Richard McBride said he had been assured by Mr. Alfred Smithers, head of the G.T.P., that the line from Edmonton to Prince Rupert would be finished by midsummer. He had received similar assurances concerning the Canadian Northern from Sir William Mackenzie.

Vancouver, B.C.—The Provincial Government has taken over the telephone line between Heriot Bay and Shoal Bay, a distance of 52 miles. All of the work that remains to be completed is the cable across Okis Hollow Channel, and Contractor H. E. Elson hopes to have this completed shortly.

Victoria, B.C.—The city engineer has reported that the road crusher, "Champion," recently purchased in Vancouver, is ready for work. It is run by a 22 h.p. gasoline engine, with an output of 60 to 70 yards per day.

Victoria, B.C.—The big Lobnitz rock crusher has had a new oil-burning apparatus installed, and is again at work on the submerged rock off Hospital Point. When the Lobnitz crusher has completed her operations at this point, within the next few weeks, there will be a clear channel with a depth of twenty feet, whereas at the present there is only fifteen feet of water. The removal of this reef will give the coasting boats easy access to the Inner Harbor, and will obviate the necessity of manoeuvring, as is now the case when boats are leaving the C.P.R. or G.T.P. wharves. Just as soon as the whole of the rock has been crushed by the powerful machinery operated by the Lobnitz, the dredges will be set to work to clear the channel.

Victoria, B.C.—It is expected that the question of the C.N.P. Company's right-of-way through the Saanich Peninsula will be settled by arbitration proceedings in the usual way. Mr. R. S. Day and Mrs. James Reid have already been named as two of the arbitrators.

Victoria, B.C.—A bridge of substantial structure has been completed over the Nanaimo River. The frame is erected on concrete piers 150 feet long, and Howe truss. The piers are built with an idea of carrying steel, should this be found necessary any time in the future.

Victoria, B.C.—The arrival of the motor tractor for No. 2 Fire Engine is expected daily. A test is to be made, so that the apparatus may be accepted and taken over from the Seagrave Company at once.

Victoria, B.C.—Four million dollars have been spent this year in British Columbia in building new roads and trails. The most notable achievement was the progress made on the Banff-Windermere motor road.

Whitehorse, Y.T.—A bridge over the Wheaton River on the government river leading from Robinson to the mines of that district, has been completed.

Winnipeg, Man.—The C.N.R. land case will not be considered by the Exchequer Court until November 17th. The case on which the court is to sit arises out of the appeal of the Canadian Northern Railway for a decision as to whether a strip of land one and a half miles long and two hundred yards wide, should be subjected to expropriation, in which case it should be compensated for heavily. The railway company claims the expropriation would kill its terminals' scheme, and therefore the land has a highly appreciated value. The matter has created considerable interest, owing to the implication of the Dominion Government, the C.N.R., the city of St. Boniface, wherein the property is situated, and the G.T.P.

Winnipeg, Man.—The premier has announced that $2,500,000 is to be expended on roads in Manitoba this coming year.

Wolseley, Sask.—An addition is being constructed to the municipal light and power plant; and a 30 k.w. generator, a 2 k.w. exciter and a new switchboard are to be installed. A second unit will thus be provided so that in case of mishap to one unit the other will carry the load while repairs are being made.

Woodbridge, Ont.—The Pinegrove Bridge, which spans the Humber River, has been completed, and is now open for both vehicular and pedestrian traffic. The structure is constructed of reinforced concrete, with steel superstructure. It has a span of 60 feet, and cost over $5,000 to build. It is sixteen feet in width.

MONTREAL MARKET LETTER

Local iron and steel circles are still in a waiting mood. At the moment there is considerable activity. Merchants are all as busily employed as they can be in shipping out orders, and boats are leaving port with full cargoes. This does not of itself indicate any improvement in actual trade. Activity in shipment is a prevailing condition each year during November, inasmuch as buyers throughout the country are all anxious to lay in their supplies previous to the closing of navigation. In a general way the closing of navigation is assumed to take place at the end of November; although, as a matter of fact, some vessels are very frequently laid up before that time, while other vessels operate right into December. Ocean steamships frequently leave the port at the beginning of December; and a year ago the Harbor Commissioners made a trip through the port of Montreal on a tug on the first day of January. So far as commerce is concerned, however, no one ever counts upon inland navigation being open after the end of November.

Dealers are still watching the situation on the other side of the border where there is every evidence of prices going even lower than they are at the present time; and prices at the present time are considerably lower than they were some time ago. There has been a somewhat striking movement in the United States in the closing down of furnaces and steel plants; and as this will mean a reduction in production, there is a possibility that a further decline in the course of prices may be arrested. Meantime, any downward trend in prices is welcomed by the consumer, although producers on this side of the line are otherwise affected. It is reported this week that the Dominion Steel Corporation has accomplished its financing at London through the issuance of $3,500,000 of 5-year 6 per cent. notes.

NEW INCORPORATIONS.

Walkerville, Ont.—Fisher Motor Company, Limited, $600,000. C. F. Garaghty, F. E. Fisher, F. W. Vollans.

Fredericton, N.B.—Atlantic Oilfields, Limited, £600,000. A. J. Gregory, J. J. Fraser, Winlow; J. B. Gregory.

Canadian Water Purifying Company, Limited, $40,000. L. A. David, L. J. M. Dugas, L. E. A. D'Argy-Mailhiot. Glengarry Construction Company, Limited, $100,000. C. A. Pope, G. Barclay, W. B. Scott.

MEXICAN EAGLE ASPHALT

TRADE MARK

Mountain Street, Winnipeg, Man., paved with Mexican Eagle Asphalt.

Mexican Eagle Asphalt is more cementitious than other asphalts.

Water will not readily injure it.

Exposure to sun and air will not cause its deterioration.

It has great cohesive strength.

It is more ductile and flexible than other asphalts.

Shocks will not crack it. It is very malleable.

We will supply asphalt having the proper penetration for your needs.

It is best adapted to Canada's climate —will not mark in hot weather—nor are snow or ice likely to crack it.

It has over 99 per cent. bitumen. Purest on the market—therefore free from deleterious matter.

It is so constituted that it will not be injured by the heat necessarily applied to melt it for paving operations.

Samples, prices, analyses, etc., on request.

THE ASPHALT AND SUPPLY CO. LIMITED

SOLE CANADIAN AGENTS FOR THE MEXICAN EAGLE OIL Co LIMITED

TRANSPORTATION BUILDING — MONTREAL

TENDERS CALLED FOR

TENDERS FOR ANNUAL SUPPLIES,

DEPARTMENT OF WORKS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on Tuesday, December 2nd, 1913.

1. Crushed Limestone (all sizes).
2. Cedar Posts.
3. Portland Cement.
4. Hardware (Pipe Fittings, Valves, Tools and General).
5. Iron Castings, Manholes, etc.
6. Limestone Dust.
7. Lumber.
8. Lubricating Oil, Coal Oil, Gasoline.
9. Rubber Valves, Packing, Hose, etc.
10. Sewer Pipe Vitrified.
11. Sewer Bricks.
12. Sand and Gravel.
13. Street Tablets.

Specification and tender form for any of the foregoing may be obtained upon application at Room 12 (Purchasing and Accounting Section) of the Department of Works, City Hall, Toronto. Envelopes containing tenders must be plainly marked on the outside as to contents. Conditions relating to tendering as prescribed by City by-law, must be strictly complied with, or the tenders may be declared informal. Tenderers shall submit with their tenders the names of two personal sureties, approved by the City Treasurer, or in lieu hereof, the bond of a guarantee company approved as aforesaid.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

City Hall, Toronto, November 18th, 1913.

TENDERS FOR IRON POSTS.

Sealed tenders addressed to the undersigned and endorsed "Tenders for Iron Posts," will be received at the Department of the Interior, up to noon of the 1st day of December, 1913, for the furnishing of fifteen thousand small and five hundred large iron posts for use on the survey of Dominion Lands, to be delivered at Edmonton on or before the 31st day of January, 1914.

Forms of tender and detailed information may be obtained from the Surveyor-General of Dominion Lands, Ottawa.

The tender must be accompanied by an accepted cheque on a chartered Canadian bank for the sum of two hundred dollars, payable to the order of the Deputy Minister of the Interior. This cheque will be forfeited if the party whose tender is accepted declines to enter into a contract to deliver the posts or fails to carry out the contract. If the tender is not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender

Newspapers copying this advertisement without authority from the Department will not be paid.

L. PEREIRA,
Secretary.

Department of the Interior,
Ottawa, October 31st, 1913.

Sealed tenders addressed to the undersigned, and marked on the envelope "Tender for 200-ton Mechanical Coaling Plants with Sandhouses," will be received at the office of the Commissioners of the Transcontinental Railway at Ottawa, Ontario, until 12 o'clock noon of the 7th day of January, 1914, for the construction and erection complete, in accordance with the plans and specifications of the Commissioners of six 200-ton Mechanical Coaling Plants with Sandhouses complete, to be erected at the following points on the line of the National Transcontinental Railway as set forth below, viz:—

One at Monk, P.Q.	.....	Mile 385.2
One at Bridge, P.Q.	.....	" 460.6
One at Fitzpatrick, P.Q.	.....	" 588.2
One at Parent, P.Q.	.....	" 705.3
One at Doucet, P.Q.	.....	" 806.4
One at O'Brien, P.Q.	.....	" 915.4

Plans may be seen and forms of tender and specifications obtained at the office of Mr. W. J. Press, Mechanical Engineer, Ottawa, Ontario, and at the offices of Mr. A. E. Doucet, District Engineer, Quebec, and Mr. T. S. Armstrong, District Engineer, Cochrane, Ont.

Persons tendering are notified that tenders must be made on the printed forms supplied by the Commissioners, and that each tender must be signed and sealed by all the parties to the tender, and witnessed, and be accompanied by an accepted cheque on a Chartered Bank of the Dominion of Canada, payable to the order of the Commissioners of the Transcontinental Railway, for a sum equal to five per cent. (5 per cent.) of the amount of the tender.

The cheque deposited by the party whose tender is accepted will be deposited to the credit of the Receiver-General of Canada as security for the due and faithful performance of the contract according to its terms. Cheques deposited by parties whose tenders are rejected, will be returned within ten days after the signing of the contract.

The right is reserved to reject any or all tenders.

By Order,

P. E. RYAN,
Secretary.

The Commissioners of the Transcontinental Railway.
Dated at Ottawa, Ont., November 3rd, 1913.

Newspapers inserting this advertisement without authority from the Commissioners, will be not paid for it.—50357.

TOWN OF YORKTON, SASKATCHEWAN.

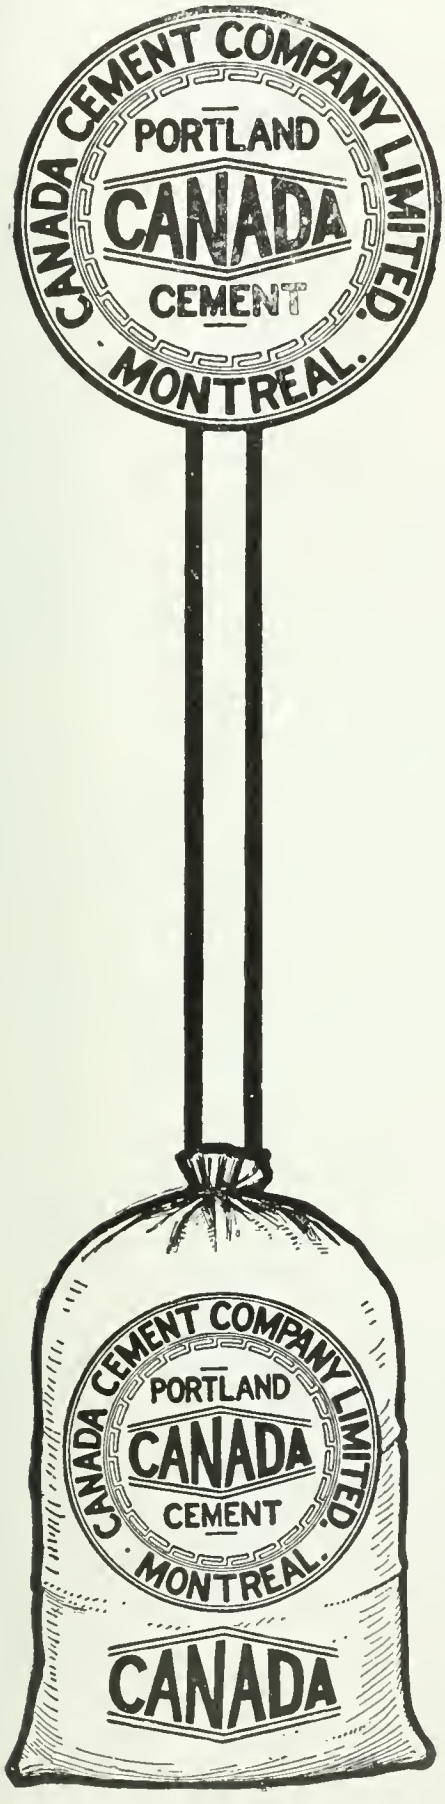
TENDERS FOR DIESEL ELECTRIC MACHINERY.

Sealed tenders marked "Tenders for Diesel Electric Machinery," addressed to T. F. Acheson, Secretary-Treasurer, Town of Yorkton, Sask., will be received up to 12 o'clock, Monday, 22nd December, 1913, for the supply and delivery of one 500 b.h.p. combined unit. Specifications and all information may be obtained upon application to M. M. Inglis, Electrical Engineer, Yorkton. The lowest tender not necessarily accepted and the right is reserved to reject any or all tenders.

T. F. ACHESON,
Secretary-Treasurer.

(For further Tenders see page 90).

PERMANENCE—



an ideal that is now attainable

THE superiority of concrete over all other materials for the buildin of permanent structures is now generally adm ted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

Tenders Called For

TENDERS FOR MACHINERY AND EQUIPMENT.

Tenders will be received by the Bowness Improvement Company at their offices, 202 Eighth Avenue West, Calgary, Alberta, until 5 p.m., December 31, 1913, for the following machinery and equipment:—

"L." One 200 k.w. Traction Motor Generator.
"M." One four panel Switch Board.
"N." One 250 k.v.a. Generator.
"O." One Vertical Single Acting Multi-Cylinder Gas Engine.

Bidders must enclose certified cheque in the amount of 5 per cent. of their tenders. Cheques of unsuccessful tenderers will be returned immediately after contracts are awarded. Specifications may be obtained from the engineer, and may be seen in the offices of *The Canadian Engineer*, 820 Union Bank Building, Winnipeg, 62 Church Street, Toronto and 628 Transportation Building, Montreal.

The lowest or any tender not necessarily accepted.

T. L. TURNBULL,
Consulting Engineer,
202 Eighth Avenue West,
Calgary, Alberta.

TENDERS FOR PUMPING PLANT, ETC.

Sealed tenders will be received by C. F. Monroe, Township Clerk, for a pumping plant for use in the new Waterworks System of the Township of Stamford, County of Welland. The source of water supply being one or more 8-inch wells.

Tenders will also be received for Wrought Iron, Cast Iron and Steel pipes, in sizes from ¾ inch to 10 inch, with valves, Fire Hydrants, etc.

Quantities and other information may be obtained from J C. Gardner, Township Engineer, Niagara Falls, Ont.

Tenders must be in the hands of the Township Clerk not later than 2 o'clock p.m., Monday, December 1st, 1913. The lowest or any tender not necessarily accepted.

C. F. MONROE,
Township Clerk, South End P.O.

MARKET CONDITIONS

Montreal, November 17th, 1913.

Bar Iron and Steel—Trade is reported active. Bar iron, $2.05 per 100 pounds; best refined horseshoe, $2.30; forged iron, $2.20; mild steel, $2.15; sleigh shoe steel, $2.15 for 1 x ⅜ base; tire steel, $2.25 for 1 x ⅜ base; toe caulk steel $3; machine steel, iron finish, $2.25.

Cement—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1 40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in. $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3 45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3 15; 1-in., $3.05.

Explosives and Accessories—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4 30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $21.75 per ton; selected Summerlee, $21.25; soft Summerlee, $20.75 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19 to $19.50 per ton, on track.

Lath—See Lumber, etc.

Lumber, etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph poles: seven-inch top, cedar poles, 25-ft. poles, $2, each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce 4-ft. x 1½ in., mill run, $3 to $3.25; pine, 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40· XXX, $2.80.

Pipe—Cast Iron—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe—Wrought and Galvanized—Demand is fair and the market steady: —¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8 50, with 69 per cent. off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. off for galvanized: 3½-inch $95 4-inch, $1.08.

Toronto, November 19th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes—Orders continue active. Lap-welded, steel, 1¼-inch, 10c. 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $14 to $15 per M., three grades.

Broken Stone—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto 60 cents.

Cement—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks, 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps—75c. and $1 per 100; case lots, 5,000, 20 per cent. off.

Dynamite—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:— 40 per cent., 16¼ cents per pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cents.

Fuses—Electric Blasting—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain—¼-inch, $5.75; 5-16-inch, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3 55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40 60; 6-inch, $52.64. Galvanized Pipe, ¼-inch, $2.86; ⅜-inch, $2.86; ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead—Firmer, $5.25 to $5.50.

Pig Iron—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green $8, with a prospect of advance. Dealers are fairly busy.

Sand—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot.....	$0 25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long ...	1.00	1.60	2.60	4.00	13.00
Double junctions.....	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes 9 inches and under, or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels—Active—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2 75 to $3 per 100 lbs. Extra for smaller sizes of angles and tees.

Sheet Copper—22c. per lb.

Sheet Steel—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized—Apollo Brand- Sheets, 6 or 8 feet long, 30 or 36 inches wide: 10-gauge, $3; 12-14-gauge, $3; 16, 18, 20, $3.30; 22-24, $3,40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 lbs. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates—3-16 inch, $2.40 per 100 lbs.

Zinc—Spelter—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, November 18th, 1913.

Anvils—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¼ to 10¾c., anvil and vise combined, each $5.50.

Bar Iron—$2.50 base.

Bars—Crow $4.50 per 100 pounds.

Beams and Channels—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick—Kiln run per M, $13; sewer pipe per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland—$2.40 to $2.50 per barrel.

Chain—Coil, 3 16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7.16, $4.75; ½, $4.50, 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper—Tinned, boiler, 26½c., planished, 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent. discount.

Dynamite—$11 to $13 per case.

Galvanized Iron—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20 $4; 18, $3.95; 16, $3.90. Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30 22, $4.30; 20, $4.10 per cw

Iron—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26 gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English or 30-gauge American, $4.90; 30-gauge American $5.15; Fleur de Lis 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.25; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7 80; 1½-inch, $9.35, 2-inch, $12.50; galvanized—½-inch $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled—3-16-in. $3.35 base; machinery, $3 base; shares $4 50 base; share crucible, $5.50; cast share steel, $7.50; toe caulk, $4.50 base; tire steel, $3 base; cast tool steel, 1b., 9 to 12½c.

Tool Steel—8½ to 15c. per pound.

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

LAYING TORONTO'S SECOND INTAKE PIPE

PLACING 2400 FEET OF 6-FOOT PIPE ON THE BED OF LAKE ONTARIO, AND CONCRETING IT INTO PLACE — CONTRACTOR'S PLANT REQUIRED — SPEED OF CONSTRUCTION

IN June, 1911, the City of Toronto called for tenders for the laying of a 6-foot riveted steel pipe from the filtration plant, situated on Toronto Island, to a point in Lake Ontario, about 2,400 feet from the Island shore. Early in August of that year, the contract was awarded to Messrs. Roger Miller & Sons, Limited, Toronto. It was in the nature of a lump sum contract, varying from the original specifications to the extent of the substitution of steel for 6 by 8-inch wooden piling throughout.

General Progress of the Work.—During the autumn months of 1911, work was begun, the operations centering chiefly upon the excavation necessary at Toronto Island, beginning at the north end adjacent to the new pumping station, and extending toward the south shore of the Island. The excavation was first made to a depth of 15 feet below lake level, and was about 85 feet in width at the water line. Fig. 1, looking south toward the lake, shows the greater part of this Island excavation. The work entailed the removal of some 20,000 yards of excavation, principally sand.

Fig. 1.—Island Excavation and Lake Operations, Looking South from Filtration Plant.

This portion of the pipe line was designed to include a tank near the shore to serve as a manhole for pipe inspection. It measures 11 feet by 8 feet 6 inches, with a depth of 24 feet. The placing of this tank in its proper position was greatly facilitated by the use of coffer-dams, which were in progress simultaneously with the Island excavation, so that by the time the latter was finished the tank was in place, and pipe-laying was in no way delayed.

One length of pipe was put in by December, 1911, and connected up with the tank. The water was particularly low at the time, the top of the pipe being only 4 feet below water level. Pipe-laying operations were, therefore, necessarily discontinued as extreme weather set in.

With the opening of spring, the contractor's plant had been put in shape, and work began with the season. Owing to a revision of the plans by the city, necessitating the lowering of the pipe line through the Island to the same level as that extending from the tank outward into the lake, after three lengths of pipe were laid work was discontinued. The pipes and tank were taken out, and the excavation was extended to a further depth of 6 feet, bringing it to an average of 21 feet below the water line. The removed portions of the line were then re-set and connections made with the filtration plant, as shown in Fig. 2.

Remarkable progress was made with the work during the summer months of 1912, despite a good deal of adverse lake weather. The entire line was laid, steel piles driven, crib placed, and the whole length concreted out into the lake as far as indicated in Fig. 3. The pipe line was ready for use by the end of January, 1913, and the job was completed with the exception of a small amount of back fill, which was placed in a short time in the early spring.

Description of Contractor's Plant.—During the winter months of 1911-12, the contractors built the required plant for carrying out the work in the lake. To cope with the

numerous exigencies attending work of this nature, particular attention was devoted to the design and construction of mechanical details, and as a result, the greater part of the plant was built and assembled especially for the work. The advisability of the extreme care taken in this procedure was evidenced later in the successful continuity of operations, and the entire absence of delays due to lack of equipment, materials, etc.

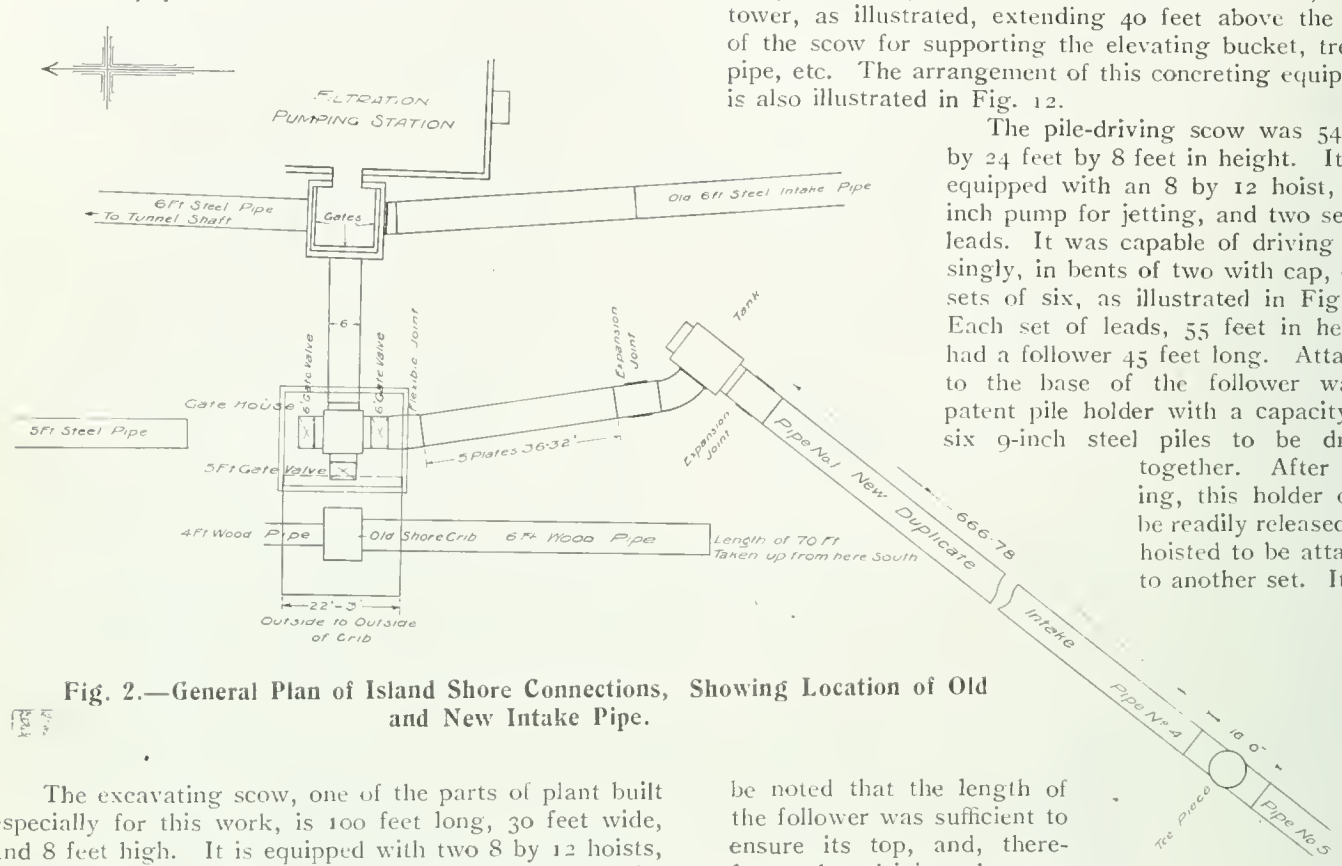

Fig. 2.—General Plan of Island Shore Connections, Showing Location of Old and New Intake Pipe.

The excavating scow, one of the parts of plant built especially for this work, is 100 feet long, 30 feet wide, and 8 feet high. It is equipped with two 8 by 12 hoists, operating two 1¼-yard clamshell buckets. One distinguishing feature is the installation of two 6 by 8 independent swinging engines. The booms used were 65 feet in length, and either derrick had a working capacity of 20 tons.

Another scow, used principally for deep water work, especially in connection with the placing of the crib at the end of the pipe line, and for the towing and placing of pipe sections, was also 100 feet by 30 feet by 8 feet. It was equipped with a steel derrick of 25 tons capacity, a 65-foot boom, a 9 by 12 hoist, and an 8 by 8 independent swinging engine. It had a clam of 1½ yards capacity. This scow, shown in Fig. 4, was also equipped with four sets of specially designed and patented thribble blocks and four powerful winches, used for manipulating the pipe sections.

The concreting scow, whose dimensions were 100 feet by 28 feet by 8 feet, is shown at work in Fig. 5. It was furnished with a derrick, an 8 by 12 hoist, a 1-yard clam, a 1-yard mixer, bins for sand and broken stone, and a tower, as illustrated, extending 40 feet above the floor of the scow for supporting the elevating bucket, tremie-pipe, etc. The arrangement of this concreting equipment is also illustrated in Fig. 12.

The pile-driving scow was 54 feet by 24 feet by 8 feet in height. It was equipped with an 8 by 12 hoist, a 6-inch pump for jetting, and two sets of leads. It was capable of driving piles singly, in bents of two with cap, or in sets of six, as illustrated in Fig. 10. Each set of leads, 55 feet in height, had a follower 45 feet long. Attached to the base of the follower was a patent pile holder with a capacity for six 9-inch steel piles to be driven together. After driving, this holder could be readily released and hoisted to be attached to another set. It will be noted that the length of the follower was sufficient to ensure its top, and, therefore the driving hammer being always above water.

The air scow was 30 feet by 18 feet by 5 feet. It was equipped with a hand derrick, jetting pump, and a 6-inch centrifugal pump directly connected to two separate engines. This pump served to remove the sand from in and around joints of the pipe sections when they were being connected up, the diver employing the suction pipe for this purpose whenever necessary in making his connections.

One important feature of these five scows was that each was equipped with an air compressor by means of which the divers were furnished with air.

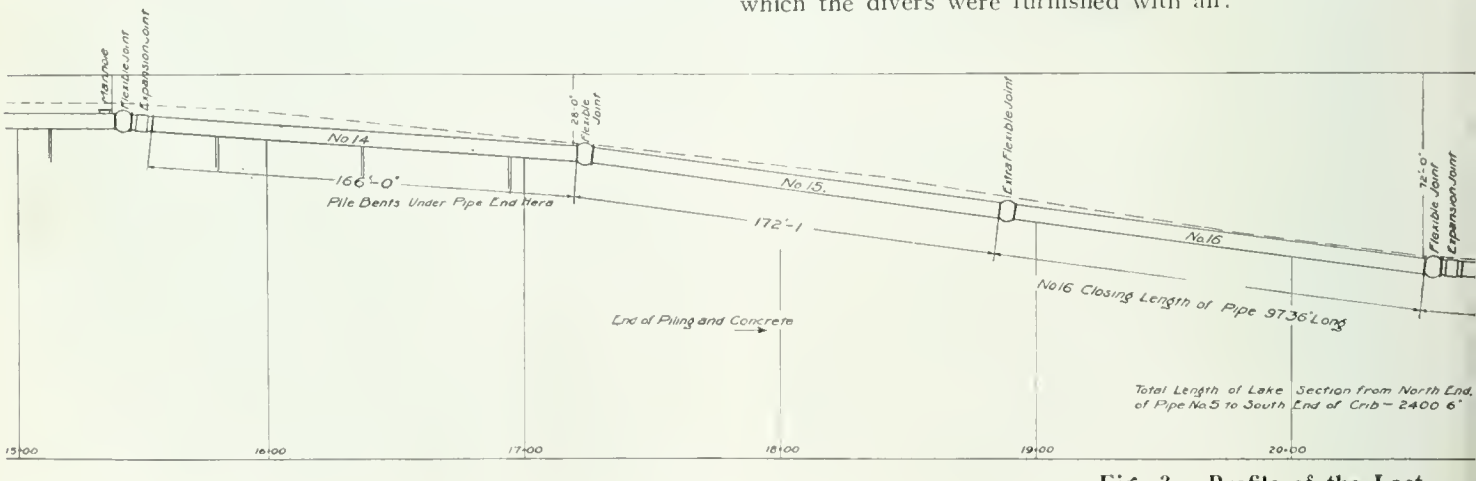

Fig. 3.—Profile of the Last

There were, in addition, several deck scows 70 feet by 24 feet by 6 feet for carrying materials such as piles, broken stone, etc. The sand required for concreting was taken directly from the bed of the lake.

Pipe Line.—The pipe line points in a southwesterly direction from the Island, as indicated in Fig. 2, which shows clearly the connections of the old and new pipe with the pumping station. The course follows the bed of the lake into about 110 feet of water. The last several sections showing its position as the decline assumes a steep gradient, is indicated in profile in Fig. 3.

The pipes were, as stated, of riveted steel, 6 feet in diameter. They were manufactured by the Canada Foundry Company, Toronto, and delivered to the city at John Street wharf. They were eighteen in number and were 166 feet in length, with the exception of several that were equipped with manholes, and were 168 feet long. Fig. 5 shows one of the sections, together with a tee, several of which were used, one at the crib, and another as shown in Fig. 2.

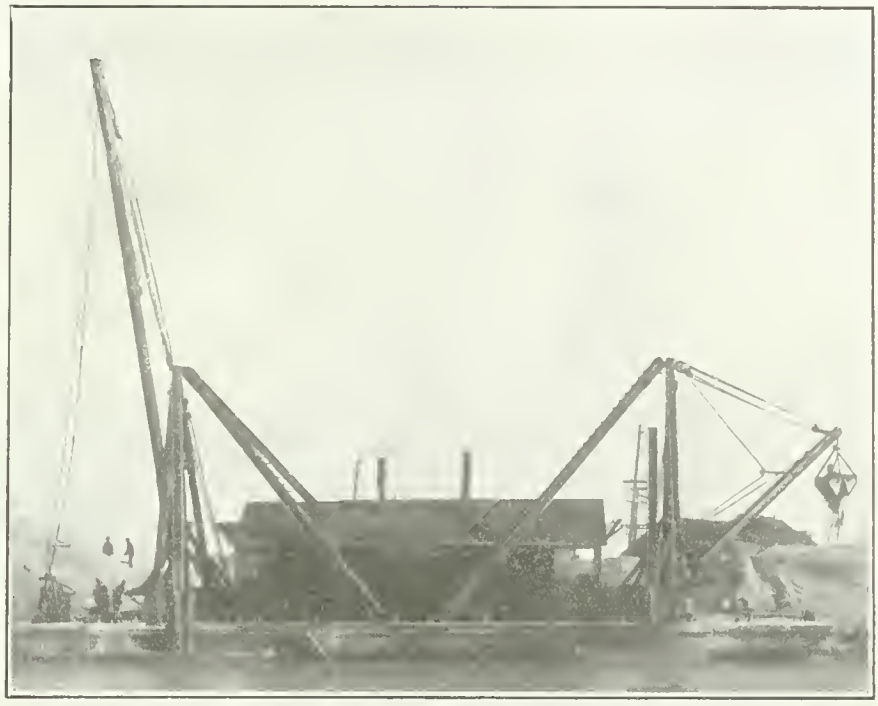

Fig. 4.—Scow Used for Deep Water Work and Pipe Laying.

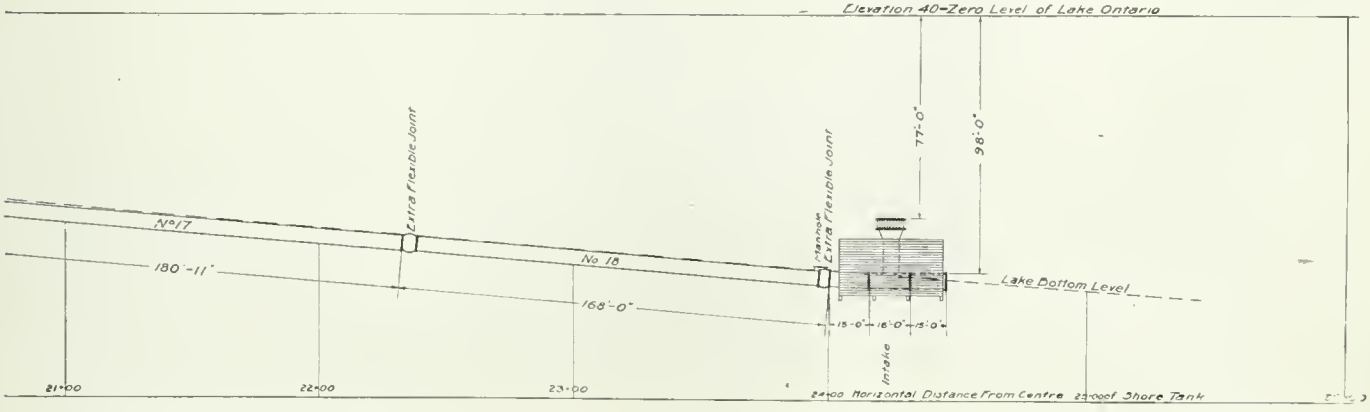
Before placing the pipes in water, they were equipped with bulkheads at each end, and rolled into the bay. They were then towed into about 12 feet of water, where, after applying two 1¼-inch cables around each end, the bulkheads were removed sufficiently to allow the pipe to be sunk by the entering water. Then, the scow, equipped with the thribble blocks and winches, was floated over it and the pipe lifted into contact with the bottom of the scow. The whole was then towed out into its proper position in the lake, and the pipe lowered into line. Specially designed knuckle joints, facilitated the removal of cables after the pipe had been lined up and a few bolts inserted. The cable arrangement was such as to permit accurate and minute changes in the position of the pipe, so that the divers found no difficulty in fitting the sections together. There were forty-four 1¼-inch bolts in each connection. At each joint, also, there was a wooden gasket of well-seasoned pine, 1 inch in thickness, with joints carefully broken, and put together with copper nails.

A 72-inch flexible joint, made by the Canada Foundry Company, Toronto, was provided in the pipe line at every stage where there was an appreciable change of grade, until the point was reached where the lake bed descended rapidly, as shown in Fig. 3. From this point to the end of the line, a flexible joint was placed at the end of every pipe section. These joints each allowed a movement from the centre line of the previous pipe of 21° 30′. Expansion joints at regular intervals each allowed a play of 18 inches. They were equipped with a 2-inch rubber ring inserted between angles, and held in position by eight or nine bolts around the circumference of the joints. Fig. 7 shows a pipe connection equipped with a flexible joint, and shows an expansion joint also.

Several points of interest arose in connection with the manufacture and delivery of these pipes that might well be mentioned. The shipping of this 72-inch pipe had an important bearing on the manufacture, as it was specified in flanged lengths of 166 and 168 feet, and the shipping of these sections allowed all circumferential joints to be shop riveted. Further, calculations were made to insure the pipe being of ample strength for safe



Five Sections of the Pipe Line.

carrying on two points. Careful measurements were made of the track, siding, curves, etc., and the site of delivery was similarly inspected to insure convenient unloading and storage.

For each shipment four 40-foot heavy capacity flat cars were used, and each length, which weighed approximately 47 tons, was loaded on cradles and swinging bunks. Fig. 8 illustrates the position of a pipe section when ready for transportation.

Fig. 5.—General View of Concreting Plant.

The Crib and Intake. — The crib which surrounds the intake is a structure 40 feet square and 25 feet in depth. It was built at the John Street wharf to a height of 10 feet, and completed after launching. It was towed out of the bay through the Western Gap, where it was loaded with about 25 tons of stone, held in suspension by three cables and a steel derrick, and then the whole outfit was towed by three tugs into the lake. Fig. 9 shows the crib on its way to the end of the pipe line.

When above its proper location, special precautions were taken to produce uniformity in the operation of lowering and to provide accurate knowledge for those at the surface, of its progress as it was being sunk. This formed one of the portions of the work where greatest care had to be exercised in order to place the crib as nearly as possible to its ideal position with respect to the pipe line, the last section of which was unplaced until the crib was finally seated. The difficulty will be understood when it is remembered that the pipe line was approximately 110 feet below the surface at that point, and there were no "bench marks" to define its relative position. The structure had been divided into sections, as shown in Fig. 10. These were then filled with stone, which was successfully carried out by means of lowering the material in a cage directed by a tow cable to whatever section was being filled. The extremity of the cable was then transferred to another section by the diver. The centre section, surrounding the tee with which the pipe line terminates, was filled with concrete to eliminate all danger of displacement of the intake. This operation, carried on at such a depth, necessitated a tremie pipe of small diameter, owing to the excessive strain upon the upper portion of its length, when discharging the concrete.

The pipe line, as stated, ended in a tee, one flange connecting with the line, its mate provided with a bulkhead, and the third placed vertically and projecting out of the crib to the intake proper, which is flared to it, and is 8 feet in diameter. It is cylindrical in form, standing vertically with closed top, while its sides are formed by a number of steel bars, as illustrated in Fig. 10, which prevent the intrusion of suspended matter of any considerable magnitude. Further, the inner part of the intake is provided with a steel plate, placed vertically to prevent the longitudinal entrance of sticks of wood, etc.

Fig. 6.—A Section of Pipe, With Expansion Joint.

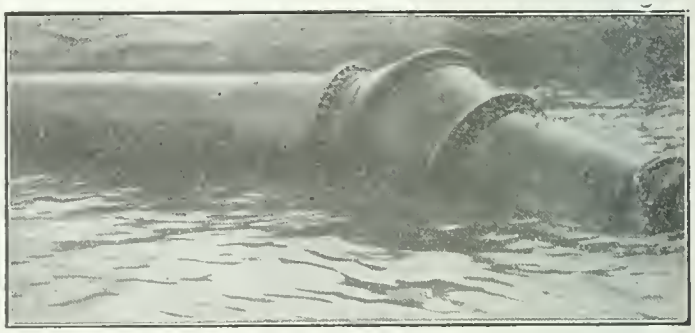


Fig. 7.—A 72-inch Flexible Joint Connected Up, and (at extreme right) An Expansion Joint.

Fig. 8.—A Pipe Section Ready for Transportation.

Piling.—Steel piles were used, it being felt that the work could not be satisfactorily done with the use of wooden piles, the depth of water, and of sand, the length of the line, etc.—conditions indicated that it would be almost impossible without tongue and grooving or some special manner of attaching one pile to its previously driven mates, to construct a permanent line. The steel piles were supplied by the United

States Steel Products Co., and were perhaps the first departure from the customary 6-inch and 12-inch steel piles previously used. They were of 9-inch section, 18 feet in length, and weighed 21.3 pounds per square foot. They were driven in panels of six (as shown in Fig. 11) for a distance of 1,800 feet on either side of the pile line (3,600 linear feet in all) or to such a point where it was deemed that the line was sufficiently low in the water to obviate all necessity of piling and concreting. A steel rod was placed across the top of the piles every 7 feet, it being ⅞-inch in diameter.

Fig. 9.—The Intake Crib, Enroute to Its Lake Position.

Concreting.—The concrete used was a 1:2:4 mix, and was placed with the use of a tremie pipe, the depth of concrete work varying from 20 to 55 feet. About 4,000 yards were used.

In connection with the shore tank, previously mentioned, the concreting of it into position was greatly facilitated by placing the forms before it was lowered into the excavation, and when properly located, it was then easily concreted.

Personnel.—The work was done for the City of Toronto, for whom Mr. R. C. Harris is Commissioner of Works, and Mr. George C. Powell, Deputy City Engineer. Mr. C. W. Allen was resident engineer on the initial part of the work, and was succeeded by Mr. A. U. Sanderson for the remainder. The contractors were, as stated, Roger Miller and Sons, Limited, Toronto, and we are indebted to Mr. A. E. Gibson, member of the firm, for most of the information and illustrations contained in this article.

LARGE CONTRACTS FOR WATER POWER PLANTS

In connection with the new enterprises of Dr. F. S. Pearson in Barcelona, Spain, known under the name of The Barcelona Traction Company, the Swiss turbine builders, Escher Wyss & Co., have secured large contracts for the supply of water wheels and pipe lines. Besides an auxiliary plant of 4,000 h.p., four large installations are being equipped by Escher Wyss & Company. Three of these utilize water from the River Ebro. The first installation comprises five units of 16,000 h.p. each under a head of 140 feet, and is nearing completion. For the second and third, the turbines are well under way. These installations comprise in one case four units of 15,000 h.p., under a head of 250 feet, and in the other, four units of 11,500 h.p., under a head of 165 feet.

The same company are supplying the water wheels and pipe lines for a high-pressure plant in the Pyrenees, built by a concern controlled by the Barcelona Traction Co. There are five turbines of 7,000 h.p. capacity each, under a head of 2,800 feet. They have obtained great experience in building plants for high heads, having built the famous Adamello power plant, operating under 3,000 feet head; the plant of the Rio de Janeiro Tramway, Light and Power Co., as well as the "Necaxa" plant of the Mexican Light & Power Co.; both these latter being enterprises of Dr. Pearson, like The Barcelona Traction Co., and developing over 100,000 h.p. each.

SOME EUROPEAN PAVEMENTS—REPORT.

MR. E. H. THOMES, Mem. Am. Soc. C.E., assistant engineer, Bureau of Highways, Borough of Queens, New York City, has returned from a tour of inspection of roads and pavements in Europe, and has presented a report containing some good information on paving materials and paving methods in numerous localities. The following is a summary:—

Pavement Studies in Liverpool.—At Liverpool, City Engineer John A. Brodie is conducting measurements of pavement wear under actual traffic. Cast iron sockets are imbedded in independent concrete supports in the sidewalk, and sometimes an additional one in the centre of the street. In these sockets can be placed standards which carry a taut wire device or a stiff wooden straight edge with sliding T square and vernier scale for the accurate measurements of the road surface. Each apparatus is adjustable so that accurate measurements can always be taken under similar conditions.

The oldest example of pitch grouted macadam in Liverpool was laid on Princes Street in 1901 and has been in continuous use ever since without any repairs. It is still in very good condition, with a mosaic surface having a good contour excepting a few slight depressions; in places it has a slight surface flush of tar still showing life. The traffic here amounts to about 120,000 tons per yard width per year. An adjoining water-bound macadam in the same street has cost from 10 cents to 25 cents per square yard per annum for repairs. The following figures show the average depth of wear in inches per annum on Princes Street:—

For water-bound macadam .....0.54 in. per year
For tar treated water-bound macadam..0.35 in. per year
For pitch macadam .....0.15 in. per year

Mr. Brodie showed a very interesting object lesson of the relative wear of the pitchmac on Princes Street and the plain macadam adjoining. A section of each had been removed and the tar washed out and the mineral aggregate separated into sizes. The plain macadam stone was all rounded with a large percentage of fine stuff, showing the wear from the rubbing and grinding effects which extend to a considerable depth in ordinary macadam, especially in wet weather. The stone from the tar macadam showed only a slight wear and rounding on the surface stones, the rest had practically as sharp edges as when laid twelve years ago.

More satisfactory results with tar macadam seem to have been obtained in Liverpool and other places in Great Britain than in most other countries. The improved results here, as well as at a few places on the Continent, seem to be due to some extent to the good quality of tar used, which in some places appears to be better than that usually obtained in the United States. Moreover, Great Britain has a more moist and more uniform climate than New York, with less extremes of frost and heat with their deteriorating effects. Tar has been used for almost all bituminous macadam work abroad, but the American natural and artificial asphalt paving cements are being introduced into Europe and are meeting with favor. It is generally considered that natural asphalt is better than tar for paving under most conditions, but in many cases it is an open question whether the results justify the usual additional expense of the asphalt.

A good practice which is increasing in favor here and abroad is to use tar in the lower part and asphalt for the wearing surface. Tar is less affected than asphalt by dampness, ordinarily in foundations, it is cheaper and more easily manipulated and for a longer period before hardening, but the asphalt is less affected by the extremes of temperature on the surface and it seems to withstand traffic better and lasts longer. Tar has been used longer and in a greater variety of methods of paving constructions in England than in any other country, but failures have occurred in all places.

Pitchmac pavement was developed by Mr. Brodie and the bituminous binder is sold by S. R. Clare & Co., Liverpool, under the trade name of "Pitchmac." The pavement contains about 13 per cent. of binder. A similar pavement was under construction upon an old cobble-stone pavement as a foundation. A 3-in. loose layer of new 2½-in. stone on top of the old foundation was well rolled and then covered from hand dippers with 1¼ gals. of tar mixture per square yard. This was then covered with a 2½-in. loose layer of 1½-in. stone well rolled and covered with about 1½ gals. of tar mixture. This was rolled hot with a 10-ton roller and covered with a layer of clean, dry, warm stone chips and rolled to a finish. Gasoline torches were used to dry the stone as laid in the roadway just prior to the tarring. The tar mixture consists of equal parts of refined coal tar and fine sand containing about 3 per cent. of powdered chalk. The hot materials were brought onto the street in two separate wagons by a traction engine from the central plant. The tar tank was covered with asbestos and black canvas, and held about 1,000 gals. The tar and sand were mixed together by a special mixing machine from which the mixture was wheeled along the street and dipped out and spread on the prepared broken stone. Mr. Brodie thinks he gets cheaper and better results with the mixture than with tar alone. The sand reduces the expense and stiffens the binder and the chalk or limestone dust seems to toughen it. Good results have also been obtained with this mixture as a joint filler and as a maintenance coating on new and old stone and wood block pavements. This idea seems worthy of a trial here.

Qwing to the great increase of traffic, the tendency abroad as well as here is to strengthen and increase a well drained stone or concrete foundation to a depth of from 6 to 12 ins. and maintain a wearing surface of stone or wood block, or bituminous material, suitable to the traffic and local conditions.

Stone Block Pavement.—Table I. shows the percentages of pavement in ten German cities which were visited. The largest percentage here and elsewhere abroad is stone block pavement. The blocks vary in size from the small 3-in. blocks in Liverpool to the large blocks used in southern Europe. I was much interested in the old Roman type of road with large irregular stone blocks, laid close together, and the later type still in use in Italy of large rectangle stone slabs from 1 to 2 ft. wide, from 1 to 3 ft. long and about 6 ins. or more thick, mostly with a sand bed and joint, some with mortar.

In France alone there are about 120 types of stone block pavements differing either in dimensions, permissible variations or taper. An effort is being made abroad, as has been done in this country, to standardize the sizes of stone paving blocks. The tendency abroad as here is to reduce the depth of block to about 5 or 6 ins. The length varies from 5 to 14 ins. and the width from 3 to 8 ins. Sand, gravel, cinders, broken stone, concrete, etc., are used for foundations. Sand, cement mortar, cinders, fine gravel, stone chips, and tarred chips are used for bed and the same materials are also used in the joints, also tar and other bituminous materials, but sand and tar are

used most. The majority of stone pavements seen abroad had fairly wide joints considerably worn.

In Germany there is quite an amount of 3 or 4-in. cubical stone block pavement called Kleinpflaster, the German word for small paving. Some of these pavements have been laid for many years and are smoother and more satisfactory than one might expect. When carefully constructed they make a fairly good economically maintained pavement for light and medium heavy traffic. A hard tough stone is necessary. The blocks are usually laid in sections with concentric semi-circular courses. This arrangement is more suitable to the irregular shaped blocks, as one side is usually shorter than the other. Blocks are also laid in random courses with edges at 45° to the line of traffic; where the joints are on an angle to the traffic, there should be less noise and less wear and the blocks may lay smoother. Small stone blocks have also been laid for many years in Liverpool, Birmingham and other places and their use is now being promoted by the Durax Dustless Roads Co., of London, under the name of "Durax Pavement." Their stone is cut into cubes cheaply and rapidly by drop hammer machines. The blocks are laid as described above and rolled with a road roller and they also use tarred chips as a bed and in the joints, which may be of an advantage. Stone chips seem to remain in the joints flush with the surface and may be better than gravel tar joints common here. Worcester, Mass., uses the stone chips in grouted joints and their stone block pavements are among the best in the country. Stone chips are not used in narrow joints or only to hold blocks in place while the joints are being filled. A Durax pavement has been recently laid in the Brooklyn Navy Yard. About a 3½-in. cubical Medina sand stone pavement similar to the Durax was laid last year in the experimental pavements on Second Avenue, near Third Street, New York City. The joints were laid at 90° to the curb. With the smaller stones it is easier to obtain a smoother dressed face, smaller joints and better foothold for horses, but there are more joints and more blocks per square yard, the expense is increased and the strength and bearing power is reduced. Narrower blocks are used on steeper grades, with stone liable to wear slippery. Larger blocks are sometimes grooved to improve the foothold. Large blocks are sometimes redressed and used over again. The larger blocks are more liable to rock unless well bedded. Softer blocks are less slippery on steep grades.

Track-ways of hard stone slabs in stone or wood block pavements are used in some cases in England, Italy and other places. In England, a similar stone slab gutter or channel is used along the curb for traffic and to carry the drainage. Curb stones are usually about 10 to 12 ins. wide and about the same depth, laid on concrete or otherwise. Curbs 5 to 7 ins. wide and 15 to 20 ins. deep are also used. Granite curb is preferred.

Liverpool and other cities have a number of very good stone and other pavements, as well as a number of poor pavements. I saw some special dressed stone brick pavements in Liverpool with such smooth surface and close joints that I thought was asphalt block pavement until I examined it closely. The small or medium sized stone block pavements with smooth, well dressed faces, laid on concrete, with close uniform joints filled with cement or bituminous grout, are of course very satisfactory, but they are very expensive and few places can afford to lay this type of pavement. Some stone pavements in Great Britain cost over $6 per square yard, at the cheaper foreign prices for labor and materials.

The Liverpool stone block pavements have been held up as a model by some tourists, and there are a number of first-class stone pavements there, but in my opinion the general average excellence does not compare with the stone block pavements of Hamburg. In Hamburg are many miles of smooth, close jointed Swedish granite pavements with blocks made about 7 to 9 ins. long, 5½ ins. wide and about 6 ins. deep, in very straight courses, at right angles to the curb except at intersections. The stone seems to wear quite uniformly smooth and the tar remains in the joints flush with the surface. This shows first-class materials and workmanship.

Wood Block Pavements.—Creosoted wood block pavements are favored in London and Paris for heavy traffic streets, where noiselessness is desired. The average life of creosoted wood block pavements in Paris has been about nine years and in London it has been about twelve years. Paris has about 3,000,000 sq. yds. of wood block pavements, or about one-quarter of its street paving.

The wood block plant in Paris, which is owned and operated by the city and lays or furnishes all the wood blocks used in Paris, is located on the Seine at Javel Quai, and is well equipped for handling the work. It has a machine which saws 16 blocks at one time and automatically discards the waste ends and sawdust, and conveys the blocks to the treating tanks. The practice there has been to only dip the blocks into hot creosote for a short time to obtain 2 or 3 lbs. absorption per cubic foot. The trend now is towards a 10-lb. treatment under pressure at high temperature, but it is not certain that the improved results justify the additional expense. The wood is carefully selected, the top and bottom of logs and tapped and untapped timber are treated separately.

The Paris plant has a capacity of about 200,000 blocks a day and furnishes over 400,000 sq. yds. of wood blocks per year. It has machines for cleaning old blocks, trimming off burrs, and sawing them smaller for relaying. These machines are portable and can be electrically operated on the street by connection with the underground electric wires.

Sheffield, England, also has a municipal wood block plant. The most satisfactory results in England have been obtained with creosoted soft wood blocks of "Pinus Sylvestris," known by the various names of Swedish Yellow Deal, Baltic Red Deal, Baltic Fir, Scotch Pine, Scotch Fir, etc., a close grained uniform wearing timber is selected. In Paris, the Landes Pine of France has been more satisfactory. These soft woods are somewhat like our short leaf yellow pine, but finer grained. The soft wood is more satisfactory because the top fibres crush down and mat together at the joints; this keeps the dirt and water out and makes the best kind of an expansion joint around each block. Soft wood wears more uniformly and the surface is covered with stone chips or grit which becomes more easily embedded in the soft wood and this makes the surface more durable and less slippery. Soft wood pavement is laid on steeper grades abroad than rock asphalt, because the latter is harder and more slippery.

The long leaf yellow pine paving block, which is usually used in this country, is intermediate between the soft and hard wood abroad. The size of the European block is about 3 ins. wide, 8 or 9 ins. long and 4 to 5 ins. deep. The usual depth of about 5 ins. permits a longer wear or allows the partly worn blocks to be cleaned, trimmed, sorted into sizes and turned over for relaying on a sand or mortar bed, or to be sawed to a uniform

depth and relaid upon smooth concrete. The 5-in. Baltic wood block does not split up as much as our 3½-in. yellow pine blocks.

Various foundations and beds are used, but the prevailing practice, especially in England, is to bring the concrete to a perfectly smooth, true finish by tamping and floating over with a layer of mortar on the fresh concrete. The concrete is allowed to set up and the wood blocks are laid directly on the smooth concrete. Sometimes untreated hardwood blocks are dipped into bituminous cement just before laying, or are laid on the tar mopped concrete. Treated blocks are sometimes laid this way.

The English practice of smooth concrete foundation probably is the best method for their deeper soft wood blocks, but it is a question whether with our 3½-in. harder yellow pine blocks there would not be more noise and pounding of the blocks and foundation and a greater expense. I would suggest that provision be made in one of our repaving contracts for laying adjoining sections of long leaf and short leaf yellow pine blocks by the English method and by our own and that complete records of the work be kept. Our method of laying wood blocks on a mortar bed and rolling with a tandem roller has some advantages and our wood block pavements are equal to those abroad.

In Vienna the wood and stone blocks are laid in courses at an angle of 45° each way from the centre longitudinal axis of the street. This has the advantage that the wheels and horse calks strike the joints obliquely and there should be less wear and noise. It also affords better opportunity for expansion of wood block pavement, but it is an open question whether the results warrant the increased cost of laying. In most European cities the wood and stone blocks are laid at 90° to the curb as is the custom here, but many of our American cities have laid wood block at an angle with the curb. One or more courses are usually laid alongside of and parallel to the curb and the railroad tracks. Abroad, wood blocks have been laid in panels with blocks alternating in different directions, etc., but sufficient advantage over the ordinary method has not yet been demonstrated.

Formerly thin wooden strips were frequently used between the courses but they are now only used in the bottom of the joints filled with mortar on light traffic streets to protect and seal the joints until the traffic mats down the top of the blocks. Grout is usually used in the joints but sand and bituminous cement is also employed. The bituminous joint is a better practice but it is a question whether the result is worth the additional expense in some cases. Clay, sand, sawdust, felt, tar, tarred oakum and other bituminous mixtures, removable wedge-shaped blocks, springs, plates, etc., have been used for expansion joints along the curbs to prevent buckling and pushing out of the curbs, but no entirely satisfactory remedy has yet been found. I was most impressed by the two kinds of compressible plates being used in Paris. This expansion joint is a bellows-like box of tar paper or thin metal, about 1 in. thick and ½ in. less in depth than the block. The box keeps dirt, etc., out of the joints until the blocks expand under traffic and weather conditions and the top of the blocks crush down and seal the joints. This compressible plate is made by G. Vallee, 5 Rue Saint Ambroisie, Paris. This looked to me to be worthy of a trial here, especially on light traffic streets. Transverse expansion joints are not so commonly used abroad. The expansion joints along the curbs are inspected and taken care of. One reason why the wood pavements in Paris do not buckle more is because the pavements are flushed with water several times a day and the blocks are kept in a more uniformly moist condition. The blocks do not dry out before they are laid or they are soaked before laying.

I would recommend that a trial be made here of the foreign practice of occasionally employing a bituminous maintenance coating on old wood blocks to waterproof the surface and prevent the blocks drying out and the joints filling up and buckling in wet weather. In Paris a large hot asphalt smoother was run over the surface of bituminous treated joints to smooth and seal the surface. Sand, grit, or stone chips are spread on the surface, which makes it more durable and less slippery.

Pavement Testing Machine.*—The National Physical Laboratory, where the English Road Board tests are made, has a new apparatus for accelerated tests of pavements. This apparatus consists of a circular roadway about 104 ft. long and about 2½ ft. wide, upon which any selected type of test pavement may be laid. On this roadway roll eight wheels which cover all parts of the roadway. The wheels are about 3 ft. in diameter and their load and speed can be varied as desired. The road can be sprinkled and the temperature varied to imitate weather conditions. This machine has not been in operation long enough to reach definite results. Engineers in Great Britain as well as on the Continent are far behind us in the matter of physical and chemical test of paving materials. It is only in the last two or three years that the foreign engineers have gone into this matter to any great extent. Most of their paving testing apparatus is of the American type, but they may develop some new ideas of value.

*See *The Canadian Engineer*, Oct. 30, 1913, p. 651.

Table I.—Pavements in German Cities.

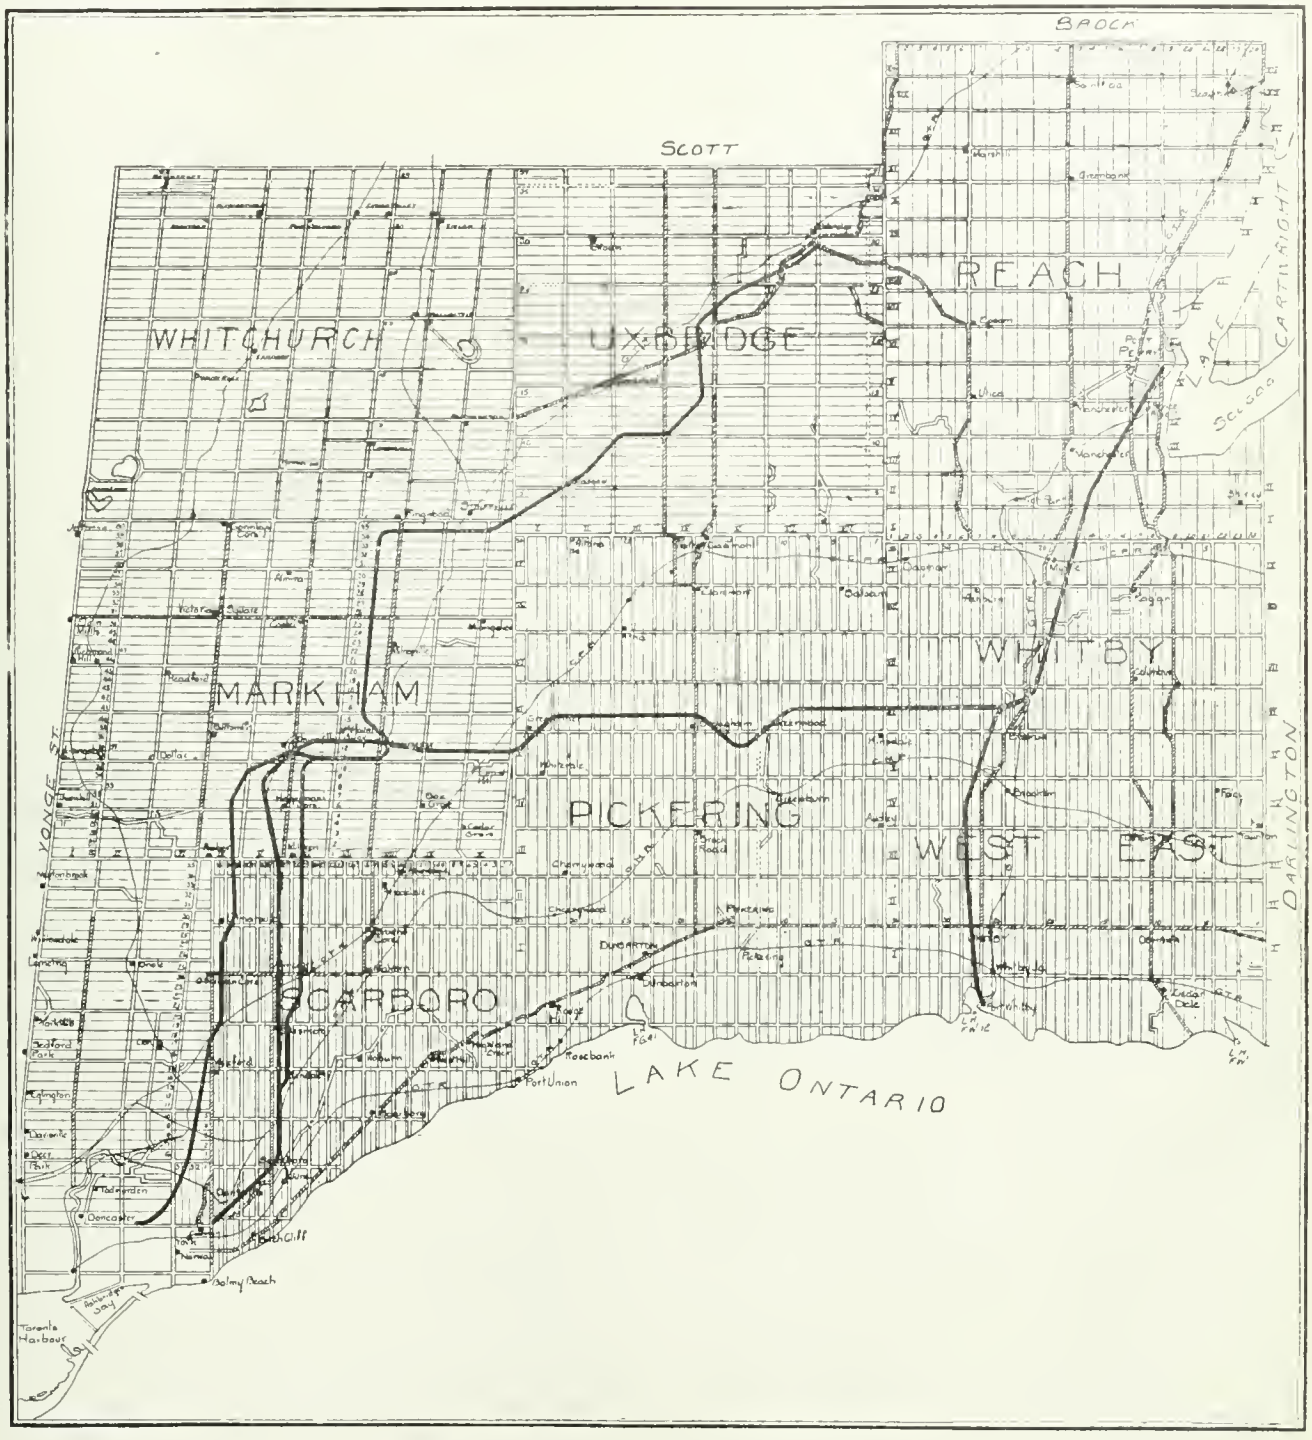
A PROPOSED MUNICIPAL HYDRO-ELECTRIC RAILWAY FOR TORONTO AND NORTH-EASTERN DISTRICT.

LAST May the municipal councils of a number of townships in the vicinity of Toronto forwarded resolutions to the Hydro-Electric Power Commission of Ontario requesting a report and estimates on a proposed municipally owned electric railway connecting the various municipalities in the district to the city. In response to these resolutions the Commission has recently submitted a report containing all necessary information with respect to the district, and estimates of traffic, cost, operating revenue, and expenses, of the proposed line. The following information is derived from this report:—

Selection of Trial Lines for Estimates.—A survey party was organized to run preliminary lines through the district to obtain data for preparing estimates on the cost of roadbed construction. A reconnaissance was first made to select routes for these lines, and it was decided that a study of three different sections should be made between the northeastern boundary of the city of Toronto as far as Unionville. From this village, both easterly and northerly, the route was more or less fixed by the centres of population, and the general contours of the country.



Surveys Made for Estimating Purposes.

The lines surveyed for estimating and study purposes are shown on the accompanying map. In the event of construction being decided upon, the actual location line may or may not follow these exact routes.

The most easterly route of the three between Toronto and Unionville was run so as to pass through the centre of Scarboro township, but it was found to be very unfavorable for construction. The middle route would give almost as good service to the residents of this township and would be much cheaper to construct. A large section of the district traversed by the third route will probably be annexed to the city before many years, and, being controlled by three large estate companies at this time, it should be an easy matter to arrange for financing their proportion of the cost. The construction of this route, with the exception of a viaduct, across the Don Valley, would be considerably cheaper than the others, and, although the line would be one-half mile longer, the terminus would be some one and one-half miles nearer the centre of the city.

The estimates on traffic, capital cost, operating revenue and expenses that are included in the report are applicable to either the middle or westerly routes. The latter line might have slightly more suburban traffic, but, this class of revenue being at low fares, the effect on the total receipts of the line is not important. The easterly route does not appear to offer any inducements, other than being the most central through Scarboro township, and, as it would be much more expensive to construct, it has not been considered in the report.

Construction and Equipment—Roadbed.—An examination of a topographical map of the district shows that there is a difference in elevation of almost 700 feet between the city and the height of land at Goodwood. This will give an average grade of .5% that cannot be avoided. The effect of such a grade on the operation of heavy freight trains would result in slow service, but, since cars and short trains only are to be used on comparatively short runs with substantial layovers at terminals, no appreciable effect should be noticed on the schedules. The unavoidable short grades encountered have been kept below 2 per cent. and curves below 5 degrees.

The character of the soil throughout the entire district, with the exception of Uxbridge township, consists of a comparatively light loam, while that in the township mentioned, is very sandy. Gravel is present in sufficient quantities adjacent to the trial lines to ensure an ample and cheap supply for track ballast. These conditions should allow for grading being done at a very economical figure.

The estimates on track construction have been prepared on a 14-foot roadbed, 80-lb. rails, 6 in. by 8 in.—8-ft. cedar ties spaced 3,000 to the mile, gravel ballast, 8-bar woven wire fence with proper gates, cattle guards, etc. These requirements should provide a good type of construction for an interurban line.

Bridging and Railway Crossings.—All culverts and bridges have been designed to carry 100-ton locomotives, in order to provide proper structures to handle any traffic that may be obtained from interconnection with the steam lines. Plate girder bridges on concrete abutments would be used in the majority of cases, but some steel viaducts will be required.

Following the practice of the present roads in the district, all overhead railway crossings were estimated upon as crossing two tracks. Half interlocking plants have been figured upon for protection of all railway grade crossings, the operation of which would be taken care of by station men or other employees whose regular duties would require their attention in that vicinity. These plants would consist of a small central tower with outside stairs. A mechanical interlocking machine would be provided, controlling home and distant signals on the steam roads, and derails and home signals on the electric line. The signals on the electric line would be located close to the crossing, so that car conductors could operate the plant themselves, when station attendants are not on duty, with a minimum loss of time.

Buildings.—Provision has been made in the estimates to cover the cost of brick passenger and freight stations at important towns, and shelters with small loading platforms at the most important road crossings.

A suitable car barn and shops, of brick construction, would be located near Markham at the junction of the Uxbridge and Port Perry lines, and galvanized iron shelters, on steel frames and concrete footings, at termini for housing cars over night.

Fireproof sub-stations would be constructed as extensions to the station buildings at Markham and Brooklyn.

Overhead Construction.—The 2,400-volt direct current system has been used in figuring the cost of the electrical equipment, but the layout and traffic should give very similar results with the single-phase alternating current or 1,200-volt direct current systems. These systems, while being more expensive in first cost and operating expenses for a short line than the older low-voltage direct current system, are necessary for a line of this type, in order that holiday traffic may be properly handled without the capital cost being raised to an amount that would cause unusually heavy expenses for normal operation. These systems have also been chosen, so that the line may be able to take care of freight traffic and be extended short distances without installing additional sub-station equipment and trolley feeders.

If it is decided to construct only a short portion of the complete line, as discussed later in this report, it would be possible to use the low voltage direct current system until such time as the extensions would warrant the system that has been figured upon.

The single catenary bracket arm type of construction has been used in estimating the cost of overhead equipment. Thirty five-foot wooden poles, spaced 150 feet apart, would be used with a 7/16 in. Siemens-Martin mild steel messenger and a 4-0 grooved copper trolley. If desired, steel poles could be used, which would increase the capital cost slightly.

Rolling Stock.—Car equipments would be equipped with quadruple 100 or 125 h.p. motors, hot-water heaters, automatic air brakes, pantagraph trolleys, double end multiple unit control, and would be provided with smoking and small baggage compartments, in addition to the regular passenger section. Cars for suburban use would be, of course, lighter and less expensive.

Main line cars would be capable of operating up to 60 m.p.h. and maintaining schedule speeds of 25 to 35 m.p.h. with stops varying from 4 per mile, to one every two miles. Comfortable trailer cars would be carried on reduced schedules, on holidays and rush hours.

Express cars for milk and light express traffic would be provided with large motors so that freight cars could be shifted or hauled short distances. Doors and other facilities would be supplied so as to provide for rapid and easy loading of milk, etc.

The locomotives estimated upon would weigh about 60 tons, and would be capable of hauling from 6 to 20 cars of freight, or three or four passenger trailer cars for excursion business. Quadruple 100 or 150 h.p. motors and multiple control would probably be used.

As snow fences have not been provided for under Roadbed Construction, provision has been made under this heading to cover rotary ploughs.

Standard steam road freight cars would be required for freight and express business. These cars could be used for large inward and outward bound shipments and by utilizing sidings between stations, the loading or unloading points could be located so as to reduce the haul by team.

Estimated Capital Costs.—The cost of right-of-way was obtained from information gathered in the field. This is a matter that rests entirely with the municipalities, and it may be possible to obtain a private right-of-way for the complete line at a much lower figure than that which has been used. The Commission has received advice from some two or three owners of land, situated between the city and Unionville, intimating that they are prepared to give a free right-of-way through their property.

The figures used in the estimates to cover the various items entering into the capital cost of the road were obtained from manufacturers, and also from the railways operating in the district.

Considerable time was given to this work and much useful information was obtained from personal visits of the manufacturers, which data will be available for further detail study in the event of construction being decided upon.

Plans and profiles were prepared of the various lines surveyed and the quantities of grading, draining, etc., figured for the different sections. Attention was also given to the probable cost of ballast and borrow pits, which information is given in the detailed estimates attached to this report.

Overhead charges of seven per cent. (7%) have been added to the total capital cost to cover engineering, interest during construction and bond discount. As the figures used in each portion of the estimate are conservative, the total cost should be ample to cover the type of line described.

Estimated Operating Revenue.—The total estimated revenue of the proposed line was divided between passenger, freight, mail, etc. Each of them has been checked by statistics of other electric lines operating through somewhat similar districts. The working conditions of these lines were carefully studied over a number of years, and readjustments had to be made as they did not all class their expenses under the same heading.

Basing figures upon a comparison of the proposed line with the electric and steam roads in the district, it was estimated that within two or three years after the commencement a revenue approximating $450,000 should be obtained.

Estimated Operating Expenses.—In preparing estimates on the cost of operation of the proposed line, liberal allowance was made to include all possible expenditures and the rates used for maintenance and operation were probably higher than necessary. The number of car crews required to give the service was determined by the inspection of train sheets, and the number of station and repair men, by a study of the requirements of other steam and electric roads. Statistics covering the cost of maintenance and repairs of track and rolling stock were available from the returns of electric lines operating under similar conditions, and the cost of this branch of operating expenses was determined by applying these statistics to the annual car and locomotive mileage from the train sheet. Expenses such as station and car supplies, general office expenses, etc., were also taken into consideration.

Estimates Prepared.—To enable the project to be examined as to the effect of the alteration of any section of the line, a series of estimates was included showing in detail the capital cost, operating revenue and expenses for a number of combinations. Five schemes were proposed, ranging in length from 71 miles to 16 miles, and in capital cost from $2,470,766 to $693,003.

Conclusions.—To build a road as set forth in the report would require some 64 miles of line, the Toronto terminal considered located in the northeast part of the city and the freight handled by a subsidiary company. The territory through which the line passes, with the exception of some 15 or 20 miles, is very fertile, and thickly populated, and examining the project broadly it has the appearance of affording a splendid opportunity for obtaining a good business from the commencement of operation. The distance from any point on the line from Toronto would be less than 45 miles, and as all these points receive a very unsatisfactory service from the present steam lines, the best of the existing traffic should be easily obtained.

PREPARATORY TREATMENT OF SEWAGE—OBSERVATIONS AND EXPERIMENTS.

CHARLES GILMAN HYDE, professor of sanitary engineering, University of California, presented very recently a paper to the League of Pacific North-West Municipalities, recounting his observations made in the fall of 1912, during an extended trip to the east, upon sewage disposal plants visited wherein particularly interesting features of preparatory and final treatment of sewage were represented. Professor Hyde also bases his remarks on many other experimental and practical installations demonstrating possibilities in the preparatory and final treatment of sewage. But in his introduction he mentions particularly the fine-screening devices of the rotary type observed at Brockton, Mass.; Reading, Pa., and Baltimore, Md., and the Imhoff tank experiments and installations visited at Worcester, Mass.; Philadelphia, Pa., and Chicago, Ill. At Worcester and Chicago, these devices were experimental in character, and were being operated in conjunction with comprehensive testing stations. At Worcester, Baltimore, and Chicago, sedimentation with subsequent sludge digestion in independent chambers was noted; though at Worcester and Chicago, these devices were again experimental. At Worcester, chemical precipitation with accompanying sludge pressing on a large and efficient scale was examined. At Worcester and Chicago, experimental sprinkling filters, and at Brockville, Reading, and Baltimore, large installations were inspected. At Brockton and at Worcester, Professor Hyde remarks that the intermittent sand filter plants are most interesting.

The following is a transcription of the paper printed as written with various divisions and headings:—

Composition of Sewage.—In considering problems of sewage treatment and disposal, attention cannot be too firmly fixed on the fact that sewage essentially consists of two more or less independent parts, each vitally important in its own particular way. Sewage consists primarily

of a very considerable portion of the water supply of a community together with such ground and surface waters as may, by accident or design, enter the sewers. In these waste waters have become dissolved a large amount of organic and some mineral matters from household, industrial, street and other wastes. In addition to the liquid wastes the sewage carries a load of suspended matters, both organic and mineral.

It is the organic matter, dissolved and suspended, which is dangerous from a sanitary point of view, is subject to putrefaction and decomposition and is capable of producing a nuisance. The suspended mineral matter requires removal in order to protect streams from unsightly deposits, and final treatment devices (like sprinkling filters and contact beds) from undue clogging. The dissolved mineral matter, while exercising an important influence upon certain phases of the problem of disposal, does not, as a rule, require removal by any special process.

The Sewage Treatment Problem.—Because sewage consists essentially of two parts—suspended solids and a liquid containing dissolved or partially dissolved organic and mineral matters—the sewage treatment problem is two-fold in its nature. It is true, of course, that crude sewage may be disposed of by a single process, as for instance, by dilution in relatively large bodies of water and by treatment in contact beds and intermittent sand filter beds, by broad irrigation, etc. The presence of suspended matters, however, greatly reduces the volume which can be effectively treated by these devices and experience indicates that, in many cases, it is extremely wise to employ some preparatory treatment in order to relieve the burden upon them. The removal of suspended matters by fine screening or subsidence will increase the volumetric capacity of such devices as sprinkling filters, contact beds and intermittent sand filters from 30 to 100 per cent., depending upon conditions. Furthermore, the removal of these matters tends to increase the efficiency of these devices even when they are operated at the higher rates which are thus made possible. At the same time their maintenance and operation are rendered simpler and less difficult. It is also undoubtedly true that water courses may, through the processes known under the general term "self-purification," receive sewage in increased volumes varying more or less directly with the percentage of organic matter of a thoroughly unstable character which is removed by special treatment.

It must be borne clearly in mind that preparatory treatment alone does not solve the sewage disposal problem unless the effluent may be disposed of in bodies of water of much size and under such conditions that sanitary laws are complied with. In California the laws governing the discharge of sewage into all waters are to be found in Chapter 374 of the Public Health Act of the State (Revised Status of 1913) and under these regulations it is necessary that all communities, industrial establishments, institutions, etc., desiring to dispose of crude or treated sewage in either salt or fresh water on the coast, tidal estuaries or in the inland streams must receive special permission so to do from the State Board of Health. Such permits will announce the particular conditions under which any party in question will be allowed to dispose of sewage or industrial wastes.

Necessity for Preparatory Treatment.—From the brief and untechnical discussion above it will be seen that the preparatory treatment of sewage is frequently an economic, as well as a sanitary, necessity. It is almost always required except where disposal of crude sewage by dilution can be accomplished without nuisance or contrary to state laws.

Even the Pacific Ocean is not in every case capable of receiving crude sewage in large volumes without producing a nuisance or even, in extreme cases, without becoming a menace to public health. A most interesting instance in point is the situation at Los Angeles where, due to complaints of beach pollution in the vicinity of the sewer outfall at Hyperion, between Playa del Rey and El Segundo, the city is advised and proposes to adopt some preparatory treatment of the sewage. The suggested minimum treatment is screening through revolving very fine mesh screens of the Weand or similar type.

A large number of disposal projects in this state has thus far involved only preparatory treatments. Just how these projects will meet with the requirements of the law and the approval of the State Board of Health remains to be seen. In almost every case, however, the preparatory treatment of the sewage will represent a correct and necessary first step although final treatment methods may require to be applied in many cases before the real solution of the disposal problems of these places is arrived at.

California Conditions as Affecting Sewage Treatment.—Speaking generally, the climatic conditions in California are strikingly favorable to all processes of sewage treatment which involve biological activities, that is, the activities of bacteria, worms and other organisms which operate to decompose, digest, hydrolyze, gasify or oxidize the organic and mineral matters in sewage. The activities of the organisms in question are greatly affected by temperature, high temperatures tending to induce rapid development and great activity and low temperatures tending to inhibit development and to lower the vitality and the activity of the organisms. Except at the higher altitudes in California freezing weather occurs but rarely and for short intervals while over large areas of the state heavy frosts are only occasionally known. In fact the conditions are such that sewage treatment works must be designed and operated with the expectation of extraordinary biological activities. In septic and Imhoff tanks it is necessary to prevent excessive scum formation and in the latter tanks, especially, large scum chambers must be provided readily accessible for frequent scum agitation and if necessary scum removal. It is to be noted in this connection that scum formation is more or less directly related to biological activity and the production of gas through the decomposition of organic matter.

Sedimentation and Sludge Digestion.

The Single-Story Septic Tank.—All single-story septic tanks, however much they may vary in shape and size and in design with respect to baffles, etc., may be classed as of the Cameron type although not necessarily infringing upon the well-known Cameron patents which are generally held by sanitary engineers in America to be non-valid. This particular matter has been discussed from time to time in detail in Pacific Municipalities. When the ordinary or so-called Cameron septic tanks were first exploited they were thought to be a panacea in the solution of sewage treatment problems and were introduced throughout the state in promiscuous fashion. In many cases they were built without careful consideration of local conditions in determining, first, whether this type of treatment would meet those conditions and, secondly, the proper proportioning and design of details.

There are certain important fundamental principles involved in the design and operation of this type of tank.

Where these have been observed and where the conditions have been favorable both as respects design and environment the results have oftentimes been quite satisfactory. It must be admitted that the single-story septic tank has represented a distinct advance, under certain conditions, over former methods of sewage pre-treatment where sludge removal by sedimentation was necessary. There are situations where, in view of its simplicity in design, construction and operation, the single-story septic tank is a logical and advisable sewage pre-treatment method. The question of odor production, to be discussed shortly, is possibly the most important consideration in determining the satisfaction of use of this device. It is also to be observed that septic sewage is more difficult to treat in final treatment devices, such as sprinkling filters, intermittent sand filters, etc., than is fresh sewage containing an equivalent load of organic matter.

The Two-Story Sedimentation and Sludge Digestion Tank.—For many years various experiments have been conducted with the hope of discovering some method of treating sewage in such fashion that the solids could be removed and digested through biological action while the liquid portion of the sewage, relieved of its suspended solids, might pass on to final disposal in a fresh (not septic) condition. Plain subsidence and chemical precipitation have solved the problem from the standpoint only of the removal of suspended matters but these processes have presented the sludge disposal problem in an acute form. What has evidently been needed is a combination whereby subsidence might be accomplished as effectively as possible and at the same time the sludge might be digested independently of the liquid portion of the sewage through processes of digestion, liquefaction and gasification which are known to operate in the so-called single-story septic tank. Various two-story tanks have been proposed for the purpose, together with certain combinations of plain sedimentation and independent sludge digestion chambers. Some of the two-story tanks suggested have been very complicated and have been aimed at the removal of colloidal substances (namely, those solids which seem to be on the border line between suspension and solution) as well as the suspended solids in the sewage. Unquestionably the best known and the simplest device and the one which has met with the most general approval of engineers because of its ready adaptability to sewage treatment problems is the two-story tank generally known as the Imhoff tank, named for its inventor, Dr. Karl Imhoff, of Essen, Germany, and used by him for the pre-treatment of the Sewage of numerous communities in the Emscher Valley. The tank has thus become known also as the Essen and Emscher tank. Its purpose is avowedly the removal of the coarser suspended solids from the sewage and the subsequent more or less complete digestion of these independently of the flowing sewage.

The Imhoff tank consists essentially of two parts or stories: (a) an upper flowing-through or sedimentation chamber through which the sewage passes with a slow forward motion such that the heavier matters, held in suspension by the velocities in the sewers, are now deposited in the chamber which has a sloping slotted bottom so steep that the sludge must slip down and pass through properly designed slots into the lower chamber; (b) a lower or sludge digestion chamber designed to receive the sludge and to retain the accumulated deposits of several months of operation while these are being worked over, decomposed and digested through the action of bacteria and other organisms. Well designed Imhoff tanks should remove from 90 to 95 per cent. of the "capable-of-settling" suspended matters and from 50 to 70 per cent. of the total weight of suspended matter in the sewage. One of the essential facts of this device is that the sewage passes from it in a fresh condition, free from the disagreeable odors so commonly associated with the ordinary septic tank above described.

Independent Sedimentation and Sludge Digestion.—As above suggested, the great difficulty with plain or coagulated subsidence has been the subsequent disposal of the enormous amount of highly putrescible sludge resulting from these processes. Recently it has been proposed to design sedimentation tanks in such a fashion that the sludge may be drawn off at frequent intervals into separate chambers where it could be digested independently of the main bulk of the sewage under very much the same sort of conditions as obtain in the digestion chamber of the Imhoff tank or in the septic tank. Experiments involving this general scheme have been conducted by the Massachusetts State Board of Health at Lawrence, Mass., by the Sanitary District of Chicago and by the cities of Philadelphia and Worcester, and works on a large and comprehensive scale for the pre-treatment of sewage in this manner have been constructed and are now in operation in Baltimore. The results of operation at Baltimore are not yet available to the writer and at the time of his visit to the plant, nine months ago, the works were scarcely in operation. The experiments at Chicago, Philadelphia and Worcester indicate that the sludge can be partially digested by this method with a consequent reduction in the bulk of solids treated. This reduction is due to the change in the character of the solids through decomposition and loss of water content. Decomposition is accomplished mainly by the bacteria and is accompanied by the liquefaction and gasification of some of the organic matter. The experimental evidence has not yet been very satisfactory from the standpoint of complete digestion of the sludge and the question of odor production is important, as will be shown later.

The Odor Problem.

General Conditions in California.—It is to be remembered that, whereas the early California was a land held in great estates, the California of to-day is a state of relatively small subdivisions while the California of to-morrow will be a state comprising very many small and medium sized communities, some extremely large and populous cities and a vast number of intensively cultivated areas which will be suburban in character. This will mean a large population per square mile and an extraordinarily compact rural development. The people of California do demand and have a right to require a complete absence of offensive odors in the vicinity of their homes. Oftentimes, without doubt, prejudice enters into the problem and odors are alleged to occur which really do not exist, at least in the degree which complainants state that they observe. On this account sewage disposal problems of certain municipalities in California are to-day by no means easy to solve and it would appear that the conditions will become increasingly difficult as time advances.

In considering any sewage treatment project the direction of prevailing winds should receive most careful attention and temperature and other climatological features should be deemed important and should be studied in their relation to each problem in hand.

Some Fundamental Considerations.—It has already been pointed out that the flow of sewage is mainly com-

prised of the water supply of a community. In places where sanitary sewers only are provided and where these sewers are laid above the ground water table the volume of sewage is entirely made up of the water supply. Fresh sewage has a distinctly mouldy or musty odor which is not generally considered to be disagreeable. It is not pungent and is too slight to be carried to any considerable distances by winds or otherwise, even from large volumes of sewage. Stale or septic sewage, on the other hand, has a strong pungent odor probably due in large part to hydrogen sulphide which is formed through the action of the bacteria from the mineral sulphates and from the sulphur in the organic compounds in the sewage. To the presence of sulphur compounds in the sewage must be mainly attributed the odors which are produced therein under the general action known as decomposition, especially decomposition taking place in the absence or limited presence of air. Foecal wastes contain small quantities of sulphur but the really great source of sulphur in sewages is ordinarily found in the dissolved mineral sulphates in the water supply of which the sewage, as stated above, is mainly comprised.

Almost all of the ground waters of California are hard and contain a considerable weight of dissolved sulphates. Certain surface waters in this state, especially those derived from coast watersheds receiving small rainfall, are also extremely hard and contain very large amounts of sulphates. The weight of dissolved sulphur in the public water supplies of the state is frequently as great as 500 lbs. in a million gallons; occasionally the figure may rise to 1,000 lbs. per million gallons and in very extraordinary cases the sulphur content may be as great as 3,500 or 4,000 lbs. per million gallons.

When sewages are exposed to the action of anaerobic bacteria decomposition sets in and various species or groups of bacteria develop and act upon it to produce hydrogen sulphide—the gas which is mainly responsible for the disagreeable odors arising from decomposing sewage, especially in septic tanks—both from the organic matter and from the sulphates present. There is some evidence that aggravated cases of production of hydrogen sulphide are caused by the desulphurization of the dissolved mineral sulphates by one or more species of bacteria. Since these sulphates are mainly in solution and are not contained in the organic matter it is apparent that if odors are to be avoided in sewage treatment works the sewage should be kept as fresh as possible and should not be exposed to the action of bacteria of decomposition prior to its final disposal by some suitable process. When the decomposition of the sludge is effected in a chamber apart from the liquid sewage the latter may be maintained in a fresh condition and may not be exposed to the activities of the bacteria in question. On the other hand, since the sludge from ordinary city sewage contains but limited amounts of sulphur either hydrogen sulphide is not formed or, if formed, is quickly absorbed or combined with iron and other salts so that it does not become apparent to the senses.

Odors With Single-Story Septic Tanks.—In the single-story septic tank, where sewage, sludge and scum are all in contact, it is apparent that the dissolved sulphates in the sewage are subject to the action of so-called "sulphur" and other bacteria and consequently may be decomposed with the ultimate production of very large quantities of hydrogen sulphide which is thrown off into the air above such tanks or is liberated from the sewage after passing from the tank. This gas-laden effluent, when aerated, spread upon land, etc., may and frequently does produce local nuisances. In one case recently investigated by the writer it would appear that the odors from septic sewage while being spread out upon land in irrigation could be detected and cause comment, if not an actual nuisance, at a distance of from 2,500 to 3,000 feet or, say, fully one-half mile.

The disposal of septic tank effluents by sub-surface irrigation or by final treatment in contact beds dosed from the bottom by automatic devices would appear to be favorable methods under certain ruling conditions. Sub-surface irrigation is adaptable, generally speaking, to very small plants only but contact beds may be used in large installations. The use of sprinkling filters with septic tank effluents is undesirable in settled communities because of the fact that the spraying of the gas-laden sewage through the air may liberate the hydrogen sulphide in such volumes as would be almost certain to produce local nuisances. Indeed, in very closely built-up communities the use of the septic tank with surface treatment of sewage, as in irrigation, is becoming almost prohibitive.

Odors With Two-Story Imhoff Tanks.—Tanks of the Imhoff type do not ordinarily produce disagreeable odors because the liquid portion of the sewage passes through them in a fresh condition while the sludge is independently decomposed in a separate chamber out of contact with the liquid in question. From the preceding statements it will be seen that the great proportion of the sulphur will ordinarily have passed through the tank with the liquid sewage without change. Doubtless some hydrogen sulphide is formed from the sulphur present in the sludge, but this is combined with iron and other salts and does not cause offence. If the flowing-through chambers of Imhoff tanks are not kept clean, if scum is allowed to form upon their surfaces and sludge to clog the slots, septic action will very shortly be established and the effluents therefrom will contain more or less hydrogen sulphide and will become correspondingly offensive. A very considerable experience with Imhoff tanks in Germany and a more limited experience with these tanks in America indicate that where they have been properly designed, and especially where they have been properly maintained, they have been satisfactory from the standpoint of the production of odors.

Odors From Sedimentation Works With Independent Sludge Digestion Chambers.—The experiments which have been conducted at Chicago, Philadelphia and Worcester indicate that independent sludge digestion is apt to be unsatisfactory from two standpoints; first, because it is difficult to secure effective digestion of the sludge under conditions which almost necessarily must obtain in plants of the type in question and, secondly, because offensive odors are created during the process of digestion. The full explanation of the manner of production of these odors is not immediately forthcoming, but it would appear that only a fraction of the disagreeable odor is caused by hydrogen sulphide and by other organic compounds containing sulphur. Much is due to other organic substances. The action of gasification in this process is apt to give rise to large amounts of dry scum which do not digest satisfactorily and which cause physical difficulties with plants of the type in question.

Some California Experiences in Preparatory Treatment.

Experiences With Septic Tanks.—A very large number of septic tanks has been built in California both by communities and by individuals. Some of these tanks are operating with fair satisfaction as far as odors are

concerned, but others are not satisfactory and are causing local nuisances on account of the strong odors which are produced therein. No chemical or physical studies showing the operating efficiency of the tanks in California, with one exception, have been made and therefore no information is available with respect to the percentage of removal of suspended matter by these devices. Data are lacking as to normal, maximum and minimum efficiencies. In certain cases, due to too active gasification, which in turn is partly attributable to extremely favorable climatic and other conditions, there has been a very excessive scum formation, so much so that this has required frequent removal and has been not only a source of trouble and difficulty in operation but undoubtedly also a cause of low efficiencies or at least of lower efficiencies than would otherwise obtain. In general it is to be noted that too active gasification is responsible for the appearance of large quantities of digested or partially digested suspended matter in the effluent. In Ohio, in 1906 and 1907, the State Board of Health made 16 separate examinations of eight plants with the result that on eleven occasions the removal of suspended matter, by weight, was nothing or actually negative and on only five occasions was there a positive removal of suspended matter. In no case was the percentage of removal as great as 50. These tanks were probably as well designed on the average as would be the case anywhere.

Experience With Imhoff Tanks.—To-day there are in operation in California only six Imhoff tanks, but a number of others are now under construction and still others are projected. It is apparent that operating experience, under California conditions, must be very limited, especially as most of the tanks in question have been operating but a very short time. Unfortunately most of the tanks thus far built have been provided with tight covers and have not been suitably arranged for carrying out the most essential features of operation. On this account septic action has in some cases taken place to a limited extent in the flowing-through chambers. In at least two cases very excessive amounts of scum have been allowed to accumulate in the scum chambers connected with the digesting chambers. In one instance at least nine feet of scum accumulated in these chambers and very little sludge had settled to the bottom of the tank. This had not digested in several months' time. In at least one tank in California sludge digestion has been accomplished satisfactorily and the sludge which has been dried out upon the bed provided for the purpose has been representative of the best that Imhoff tanks have been able to accomplish.

Experiences With Sewage Screens.—Practically no data have been gathered as yet in California with respect to the efficiency of sewage screens under practical working conditions. Recently interesting data with respect to the amount of suspended matter which may be removed from sewage by such devices have been experimentally gathered at Sacramento and at Stockton. Fine rotary screens of the Weand type are advised to treat the sewage of Los Angeles at the Hyperion sewer outfall and one unit of this general type is being installed at the Anaheim Sugar Factory for the pre-treatment of its wastes. While in general it may be remarked that the field for fine screening of sewage is comparatively limited in California, it may also be said that there are undoubtedly numbers of conditions and circumstances under which the process might be used with success. Greater attention should be paid in this state to the rough screening of sewage, especially in conjunction with pumping devices.

SPEEDY REINFORCED CONCRETE CONSTRUCTION AT FORT WILLIAM, ONT.

A SAMPLE of reinforced concrete construction that is probably a record for Canada, or, at all events, an unusual example of speedy erection, taking into consideration the handicap which severe frosts present and likewise the lack of facilities for quick transportation, is a building here referred to and illustrated in several of its stages of construction by the accompanying photographs. It is built of reinforced concrete with an exterior of brick. Its dimensions are 100 feet by 125 feet, and consists of five stories and a basement. Its foundation is 8 feet below sewer level, a total depth of 20 feet below the ground surface. The building is set upon 1,300 piles, varying from 40 feet to 55 feet in length, according to the variation in the depth of rock over the area.

Fig. 1.

The contract for the erection of the Grain Exchange was awarded to A. C. Stewart & Company, general contractors, Fort William, and was signed on the 14th of February, work commencing the following day. There was a depth of 4 feet of frost to remove in the excavation. This was undermined and shattered with a 2-ton pile hammer falling 50 feet. Excavation began on February 17th, and the first piles were driven on March 5th. Fig. 1 shows the progress that had been made up to March 15th, the excavation work and the pile driving proceeding simultaneously. Concreting the basement began on April 2nd. Piling was finished on the 11th of the month,

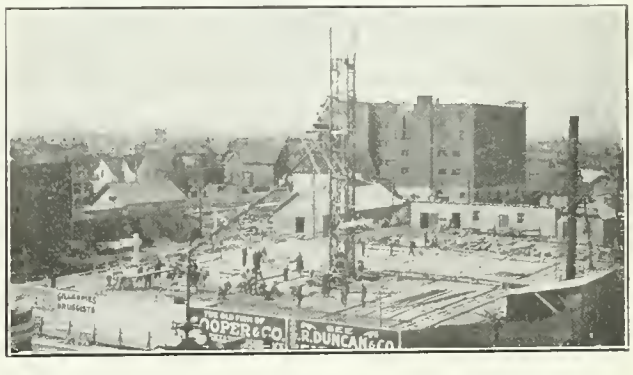


Fig. 2.

and excavation work completed on April 28th. A 4-inch Emmerson pump was installed to prevent undue flooding of the foundation work from the spring melting of snow and ice.

Fig. 2 illustrates the progress which had been made up to May 5th, at which date the concrete was entirely laid in the basement and ground floor, and the building was, so to speak, at ground level. The first floor was

poured by May 15th, the second floor by May 23rd, and so on to the 6th, or roof, the pouring of which was completed on June 21st. Fig. 3 shows the progress up to May 20th, and Fig. 4 shows its appearance on June 21st, when the concreting of the roof was completed. At this date, also, the brickwork was up two stories, and the majority of the pyro-bar partitions were in position.

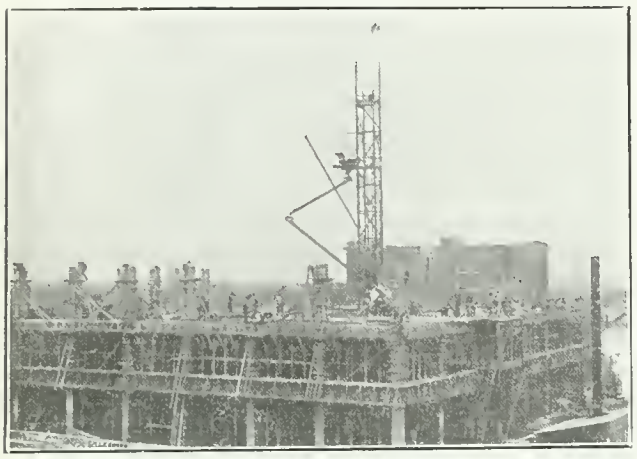

Fig. 3.

The Dominion Grain Commission leased the entire third floor of the building, and for their inspection room, designed to carry 300 lbs. per sq. ft., a test of one slab was taken when the concrete was forty days old. This particular slab was 16.0 feet by 17.4 feet in dimensions, and experienced a deflection of 0.10 under a test load of 500 lbs. per sq. ft., a total of 70 tons.

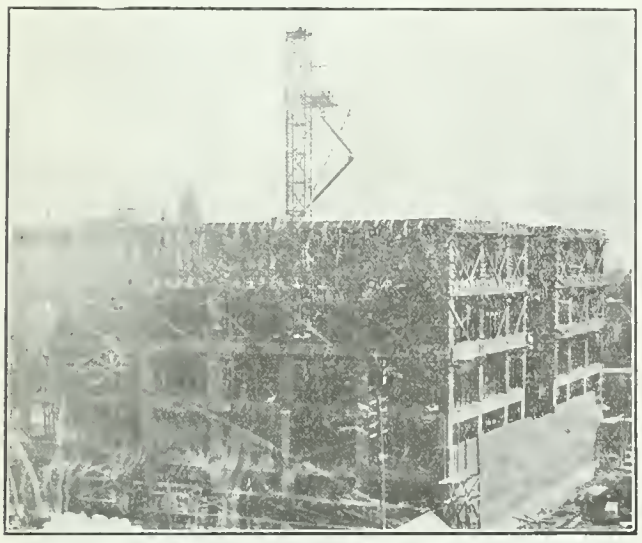

Fig. 4.

The entire building was bricked, and the roof finished, on August 16th; while the wood trimming, painting, and terazzo floors were finished by the end of September. The only items that prevented the contractors from handing over the building to the owners on October 1st were owing to unavoidable delays in the delivery of the elevator machinery, and of the marble for the main entrance. Notwithstanding this, the Grain Commission occupied the entire floor the first week in October, a number of offices were occupied the following week, and the building was accepted by the owners a few weeks ago, the total cost being $320,000.

While any statement of this construction surpassing previous records might be termed erroneous by various companies in the United States, it must be remembered that building construction in the south has not to contend with heavy winter frosts and snow; with an excessive run-off in the spring due to melting snow and ice, and the long and difficult means of transportation which contractors have frequently to overcome in Canada.

While it is not possible to make speed comparisons of buildings that are materially different in construction, the following data of some recent contracts in the United States may be of interest:—

A building in Jersey City, N.J., is 100 feet by 100 feet, with five stories and basement. It comprises soil bearing foundations and flat slab floor construction. The contract was signed February 20th, 1912, and the building substantially completed September 1st, 1912.

Long Island, N.Y., has a building 60 feet by 355 feet, three stories. The contract was signed September 11th, 1912, and the building was completed on January 1st, 1913. Concrete piles were furnished by the owners, and the contractor, for this portion of the work, began operations about August 15th.

There is a warehouse at Jacksonville, Fla., that is 110 feet wide, 60 feet deep, with five stories and basement, one-half of the foundation resting on wood piles. The contract was signed November 23rd, 1912, and completed July 15th, 1913.

A 175-foot by 258-foot three-story factory building at Baltimore, Md., rests on concrete piles. Its foundation work began February 1st, 1913, and the building was accepted as completed on May 7th.

An eight-story building, 60 feet by 200 feet, with soil bearing foundations at Brooklyn, N.Y., was completed just seven months after commencement, in 1911.

RESOURCES OF THE PEACE RIVER DISTRICT.

Possibilities of the Peace River district and the far northwestern territory through which winds the Mackenzie River were the subject of an interesting address given recently by Mr. Charles Camsell, of the Dominion geological survey, under the auspices of the Vancouver Chamber of Mines, at Vancouver. Mr. Camsell characterized that district as unparalleled in the fur trade at present, and a future country where mineral will be largely produced, from all present indications. The mineral indications found there by Mr. Camsell gave indications of probably large deposits of copper, zinc, silver and lead, as well as gold.

In addition to its other vast resources there would be oil. Oil and tar exudes from the earth in areas which were spread over from 150,000 to 300,000 acres. These, he said, were the best possibilities in the world. Oil, and where to find it, and find it in big quantities, is Britain's most intensely interesting problem just now, owing to the fact that the use of oil fuel is growing to such a degree that it is but a question of time when all the big ships will of necessity have to use it as the cheapest and best-known fuel for economical operation.

Mr. Camsell also spoke of the geological study he had made of the Similkameen district of British Columbia, where he spent considerable time. The general formations were for depth and permanence of the mineral lodes, he said. The district was fast being opened up by large mining interests, and was receiving a careful prospecting, as the result of which in time the Similkameen district would become one of the most important from what knowledge his studies had gained for him while in that district.

WATER IN OIL WELLS.

This subject has been receiving a good deal of discussion in the technical press. It is an important one, as the importance of incursion of water into oil wells cannot be emphasized too thoroughly or too soon. It would appear, from recent reports from one or two important oilfields in other countries, that this problem has not yet been solved in a manner efficient enough to obviate the abandonment of what might ultimately have been producing wells. It seems extraordinary at this date that, although every drilling man of experience recognizes the danger of the inflow of water, no device or method has yet been introduced which can be relied upon to exclude water from oil wells—to such an extent, at least, as would not involve their abandonment. Great attention has been given to this matter by some of the most experienced both in European and American oil-boring practice, and yet no satisfactory solution of the difficulty has been discovered. The existence of such problems as this affords ample justification even of the necessity of the formation of a technical institution where experienced drillers and others could meet together and endeavor to discover some more efficient method of dealing with the question than is at present available. Now that the Canadian oil industry has received a decided impetus by the discovery of important oil indications in Alberta, and by the proposed adoption of oil as a fuel in numerous branches of industry in the west, an investigation of the water problem would not be out of place.

THE ENGINEER AS AN EXPERT WITNESS.

An interesting reference was made in the article by Walter J. Francis, C.E., entitled "Engineering as a Profession," (*The Canadian Engineer*, Nov. 6th, 1913, page 685), where it is stated that the engineer's remuneration for professional services in the law courts is something like $1.25 per day. This question regarding the inadequacy of fees to professional witnesses has been under consideration a great deal in England during the past season. It was aroused by a complaint made by an association of shipbuilders that the allowance for expert witnesses was too meagre in the case of Board of Trade inquiries, and the result has been the formation of a special committee of representatives of the Institution of Naval Architects, the North-East Coast Institution of Engineers and Shipbuilders, and the Institution of Engineers and Shipbuilders in Scotland, to consult as to whether representation should not be made to the Board of Trade regarding this inadequacy of fees. It appears that an act, passed in 1894, provides for the payment of expenses in respect of the attendance of witnesses at Board of Trade inquiries on the same scale as in the ordinary courts. The Board, however, allows only $15.75 and first-class railway fare. Under the County Court rules and the High Court Orders, which apply to Board of Trade inquiries as well as to the ordinary courts, an extra fee of from $5.25 to $26.25 may be obtained for "qualifying to give evidence." The consultative committee of the North-East Coast Institution of Engineers and Shipbuilders think that while the Board of Trade has no jurisdiction to raise the fees proper, it might in practice allow expert witnesses and leading officials of shipbuilding firms attending inquiries and giving evidence an additional qualifying fee, in terms of the Rules of Court, of from $5.25 to $26.25, making a total of $21 to $42.

But in Canada, although members of other professions are, generally speaking, given some recognition for their qualifications for giving evidence, the engineer is reimbursed for his services by a dollar and a quarter per day, there being no consideration given his ability and training more than if he possessed only that acquired by the handling of pick and shovel.

FIRE-RESISTING CONCRETE.

Of recent years complete confidence has been established in the fire-resisting qualities of properly constructed concrete. These, combined with its durability and strength, render it particularly suitable for the construction of buildings in which more or less hazardous occupations are to be carried on, or which are to be erected in areas wherein it would be difficult to cope with a conflagration.

For fire-resisting concrete quartz sand should be used, and broken trap rock is, perhaps, more suitable than any other substance. Limestone is probably next in order of suitability, although it will eventually run into a crude form of glass or be calcined; but that will not take place until the cement itself has been disintegrated. Contrary to the commonly received opinion, cinder concrete is not unsuitable from a fire-resisting point of view. The chief objection to its use is that it is far from strong. Heat does not affect it to a great extent; indeed, it has been found that small pieces of coal embedded in concrete have remained entirely unaffected by heat. That was due to the low heat conductivity of concrete; indeed, it might almost be said that it is an insulator of heat—so much so, at any rate, that the hand can be borne on the top of a slab of concrete five inches in thickness under which a fierce fire has been raging for five hours or more.

This non-conductivity is well shown by the following account of a steam conduit built of concrete. The conduit was about 500 ft. long, and was built between a mill and a boiler-house, and was made just wide enough to take two steam pipes 6 in. in diameter and two smaller pipes. After the pipes had been laid in position a concrete cover was constructed over them, so as to render the conduit proof against any moisture in the soil or surface water. The conduit was carried some 2 ft. 6 in. below the surface—not sufficiently deep to be beyond the influence of the specially heavy frosts which were periodically experienced in the neighborhood in which the conduit was laid. The concrete troughing was left open at both ends, to make it easy to ascertain whether there was or was not any leakage. It was assumed that if any vapor was found to escape from either end of the conduit there must be some leakage which would permit the water to vaporize. The conduit was allowed to dry thoroughly, which took about two weeks; but no vapor has at any time been visible, and the loss of heat, which has been measured, through the concrete is so small as to be negligible.

The province of Quebec has constructed about 225 miles of macadamized roads and about 60 miles of gravelled roads this year. In all about 900 miles of roads have been constructed or have undergone extensive improvement, according to Hon. Mr. Taschereau, Minister of Public Works. The King Edward Highway is practically completed and about 40 miles of roads between Quebec and Montreal are at present under construction.

LETTERS TO THE EDITOR.

Further Discussion of "Bending Moments in Flat Slabs."*

Sir,—The paper by Mr. V. J. Elmont on "Bending Moments in Flat Slabs," published in your issue of September 25th, 1913, and the discussions which have followed it, disclose but one real criticism of the flat slab, namely, its lack of reinforcement, in a number of systems at least, at right angles to the edges of the slap in what might roughly be called the middle third of the space lying between the column centres.

That negative bending moments exist across strips having these edge lines as axes must be admitted by all who give any consideration to the matter. Their magnitude is unfortunately a source of much difference of opinion. Mr. Elmont estimates the maximum negative moment at the centre of an edge line and at right angles to it as $gl^2 \div 28.8$. The researches by Mr. Frank J. Trelease conducted on rubber models for the Corrugated Bar Company indicate a moment which, when expressed in Mr. Elmont's notation and in terms of the span centre to centre of columns, becomes $gl^2 \div 87.5$. It would be interesting to have Dr. Eddy's estimate of the magnitude of these moments, but notwithstanding Mr. Elmont's assertion that he (Dr. Eddy) had found far greater values for them than his critic had indicated in the original paper, Dr. Eddy nowhere in his treatise on flat slabs, so far as the present writer has been able to ascertain, attempts to assign a value to the particular moments under discussion. His brief consideration of them is concluded by the following general statement:—

"The curvature of these sections (normal to the edge lines) is controlled by the stiffness of the mushroom heads, which is so great as to make the curvature very small. No considerable tensile cross stresses are consequently to be apprehended; but in case the stiffness of the head were to be decreased, stresses might arise such as to develop longitudinal cracks over the middle rod of the side belts." Indeed, it could scarcely be expected that the advocate of a system without reinforcement for the resistance of a particular stress, would establish mathematically the existence of such a stress unless it were so small as to not exceed the safe resistance of the material at the section under consideration. The comparative silence of Dr. Eddy on this matter can scarcely be interpreted otherwise than as an admission of a stress condition somewhat difficult to meet with the rod arrangement of the mushroom and certain other systems.

The writer does not, however, support the view that the tensile stresses across the edges of flat slab panels are of necessity seriously objectionable. Undoubtedly the size of the column heads and the width of the diagonal belts of rods have an important bearing on the magnitude of these stresses. It is a fundamental principle of structural engineering that a load will divide itself among a number of resistance-paths in proportion to the rigidity of those paths. If, therefore, strong resistances are supplied by stiff column heads and plentiful diagonal reinforcement, the floor load will travel to the columns largely along these lines. But in a reinforced concrete slab, necessarily continuous in construction, one cannot force the loads to exclusively follow paths marked out by reinforcement steel. The presence of the concrete as a unify-

*This article appeared in *The Canadian Engineer* for Sept. 25th, 1913, and was discussed by Dr. H. T. Eddy and Mr. V. J. Elmont in Nov. 6th issue.

ing mass involves the transfer of a certain part of the loading to the side belts of rods along lines at right angles to them, and tension along these lines cannot be overcome, no matter how much diagonal reinforcement may be used. But if the tension is small, as it probably is in well-designed slabs, it should be no more objectionable than the tension which often exists over the tops of beams and girders in floors of ordinary reinforced concrete construction due to under-reinforcement for negative moment or the placing of the steel so low as to be quite ineffective for the purpose for which it was intended. In any event, it is not a question of the ability of flat slabs to support the applied loads with entire safety, but simply one of the probable effect of the existence of certain small edge cracks on the embedded steel or on the finished flooring. Corrosion tests conducted in Germany by Professor E. Probst have shown that cracks on the under side of concrete beams produced by stressing the embedded steel up to nearly the breaking point have no deleterious effect on the metal, so that it would appear safe to dismiss the former effect as of no great consequence. Cracks in the finished flooring would be objectionable only if visible, and as far as the present writer knows, these have not been observed in buildings with flat slab floors.

C. R. YOUNG,

University of Toronto, November 20th, 1913.

* * * *

Discussion of "Bending Moments in Flat Slabs."

Sir,—In an engineering discussion, fairness is presupposed on the part of those taking part therein, unless they have been misinformed. Mr. Elmont's discussion, noted in your issue of November 6th, hardly comes up to this standard.

He credits Mr. Mensch with being the first, to his knowledge, to have applied flat slab to actual building. The writer has noted Mr. Mensch's statement that he had used flat slab construction in the Armourdale Plant of the Procter and Gamble Company, and was sufficiently interested to write to the company for information, and the reply from their superintendent, Mr. Robert Anderson, states that 'the only concrete used in these buildings was the reinforced concrete foundations and footings. The buildings themselves were mill construction." Concerning the flat slab, Mr. Anderson states in another letter: "We beg to advise that this floor slab is in one portion of our Kansas City plant, and covers a room 100 feet square. This floor slab is directly on the earth and is designed to support tanks which have conical bottoms, distributing the weight of the entire tank on six columns around the periphery and one point in the centre. These tanks will hold 396,000 pounds of water each, this being divided on the seven points mentioned." Thus Mr. Elmont's knowledge of what Mr. Mensch accomplished seems to be somewhat misleading; that is, supposing the superintendent of the Procter and Gamble Company is familiar with the character of the construction of the buildings.

Mr. Elmont's remarks about Matrai are equally interesting. A mere resemblance in plan of the arrangement of reinforcing hardly proves the construction to be flat slab. Matrai's idea, as he has expressed it freely, was to put up a building which would not depend on the strength of the concrete. He would provide wires for tension members and girders to resist the pull of the wires, the concrete being merely spread upon the wire to distribute the load over these suspension members. A cheap concrete was to be used, cinder concrete, or even a natural cement mortar. The office of the concrete being merely secondary—a means of distributing the load over a steel system, and yet Mr. Elmont would have the readers infer that Matrai arranged the reinforcement for flat slab, a form of construction in which the motive was entirely different.

Equally interesting is Mr. Elmont's representation of the unreinforced or helpless character of the concrete in his so-called unreinforced areas. Placing the steel in the concrete does not prevent tensile deformations in the tensile zone. It merely limits or controls the magnitude of these deformations. If Mr. Elmont will consider the curves of flexure on which Grashof theory is based he will see that the tensions in the areas which he refers to are normal to the lines joining the columns, and hence can be resisted and controlled by steel in the same direction in the top of the slab in the area about the column, rather than in the areas midway between columns, and that steel in this area has greater load carrying power, hence designers of the Turner slab prefer to limit and control these stresses by steel placed in accordance with their standard design.

The writer will frankly agree with Mr. Elmont that the Deere and Webber test was not a sufficiently severe test to warrant very serious consideration. It was not the test load that was required by the city of Minneapolis, which demands ordinarily that the test shall be double the working load. On the other hand, when we bear in mind the fact that it requires a drop of only 23 degrees Fahr. to exceed the normal tensile strength of concrete, providing the ends of the slab are fixed, positive conclusions cannot be drawn from the discovery of a check in the slab. The safe plan is to see that the steel is there to take the tensions, and to count on the concrete for compression. A microscopic check which cannot be found except by the use of a magnifying glass should cause no one having an engineering education to consider the defect as sufficiently serious to merit extended discussion. The writer makes this statement, not with a view to advertising someone else, but merely as a question of fair dealing which should be recognized on its face as such.

Interesting misinformation is contained in his article as to what floors of ordinary buildings are designed to carry. The Turner slabs are designed for a working stress on the steel of 13,000. Sixteen thousand pounds working stress is used by the average structural steel engineer, and doubling the working load on a structural steel building, thus increasing this stress to 32,000 pounds, makes the stress in the steel only a shade under the yield point value of the metal, and eliminates the factor of safety. In the concrete structure, with 13,000 pounds working stress, we have an opportunity to put on 216 times the working load, live plus dead, without straining the steel more than would be the case in doubling the load on the structural steel building, and we have not anywhere nearly reached the ultimate strength of the construction. A mushroom slab which would ordinarily be rated at a 350-pound working load has been loaded to 3,300 pounds per square foot in the centre of the slab and deflected and bent out of shape 9 inches and still carried the load without further deformation. These are facts which rather upset Mr. Elmont's contention.

The average critic of flat slab construction, it would seem to the writer, has never heard of the fundamental theory of work enunciated by Clapeyron, almost seventy years ago, which principle has been developed so that the

theory of work is used to-day in the computation of stresses in statically indeterminate structures in determining the deflections in all bridge structures, and forms the ground work in a large part of the science of structural engineering.

The consideration of the principle that the external work of the load must equal the internal work of deformation and that the active energy of the load passing through the height of deflection is stored up as potential energy within the slab, and a consideration of the manner in which this potential energy is stored up, should be sufficient to cause Mr. Elmont to admit frankly his error in the premises. If the radial deformation about the head at a given section at a distance R from the centre of the column and within the line of inflection be called ΔR, then the circumferential deformation must be $2\pi\Delta R$, and we can readily show that the amount of energy stored up in the circumferential direction is fully three times that which is stored up in the radial direction, and to assume with that in view that the same formula can be applied to the flat plate that is suitable for the beam strips becomes as absurd on its face as Mr. Elmont's endeavor to attribute to the man who put in a concrete foundation resting on the earth throughout, the origination of flat plate construction in commercial form in the floors of the warehouse buildings, a form so popular that it is almost universally imitated by all who are successful in concrete construction. Certainly it would seem that a reasonable degree to fairness ought to exist among engineers, and that they should not, without personal knowledge, undertake to assign the credit for a radical departure in modern construction to those who did nothing whatever toward materializing such construction. Hearsay evidence seems to be accepted without question by men with no legal training and frequently the mere assumption that certain conclusions without proof are a mechanical fact and are based on natural laws is also unfortunately a failing of the laymen, and it would seem to be the office of a reputable engineering paper to do all in its power to eliminate such error.

It should be noted that Mr. Elmont's final quotation from Professor Talbot, in the last paragraph of his reply, is with reference to the very cracks in the Deere and Webber test which were discussed in quotation from Professor Talbot made by Dr. Eddy, in which it was explicitly stated that "so far as any one knows, they are not detrimental to the structure." Mr. Elmont evidently disagrees with Professor Talbot on this point, but he will have to adduce far more convincing reasons in support of his position than he has yet given before the profession will be willing to agree with him rather than Professor Talbot.

C. A. P. TURNER.

Minneapolis, Minn., Nov. 11, 1913.

* * * *

[Mr. Elmont was furnished with a copy of the above communication, and in reply, he has transmitted the following.—Ed.]

Sir,—In November 6th issue of this journal the writer answered a discussion on his paper "Bending Moments in Flat Slabs," sent in by Dr. Eddy. Now Mr. C. A. P. Turner takes the word from his mathematical assistant, continuing his discussion.

In answering, the writer considers it necessary to remind Mr. Turner that the point of the writer's paper was, to show theoretically what he considers has been shown practically by Prof. Talbot's careful testloading of the Deere and Webber building, i.e., that there are heavy negative bending moments perpendicular to the sides of a flat slab panel; these should be provided for by placing reinforcing steel where the moments act and in quantities depending on the value of the moments. Most flat slab designers, including Messrs. Eddy-Turner, do not adopt this arrangement.

Messrs. Eddy-Turner's practical reason for not wishing to adopt the writer's recommendation seems to be that numerous testloadings of flat slabs have shown that their design is safe, these slabs having been designed in their usual way with an allowable steel stress of 13,000 lbs. per sq. in. This argument, however, carries no conviction to the writer's mind; firstly, because a safe structure according to the Eddy-Turner definition is one which can "carry twice the live load without failure and can do this for months at a time without signs of distress"; as explained in the writer's answer to Dr. Eddy this definition is unsuitable to efficient structural engineering. Secondly, the writer thinks that no conclusions about the point of his paper can be drawn from Messrs. Eddy-Turner's testloadings because they have not been conducted carefully enough—as it also was said in a recent discussion in the American Society of Civil Engineers—"they are largely confined to the loading of single bays and deformations or strains not measured."

The second and third last paragraphs of Mr. Turner's discussion are, the writer assumes, intended as a theoretical explanation of his standpoint; the main words contained in them seem to be statically indeterminate structures, Clapeyron's theory and potential energy. Though the writer has had the opportunity to calculate and build a number of statically indeterminate reinforced concrete structures, and is familiar with Clapeyron's theory and the definition of potential energy, he is at a loss to get any sense out of these two paragraphs, and therefore is unable to pass any opinion about the wisdom contained of them.

The writer had no reason to doubt the source from which he received the information that Mr. Mensch was the first engineer who used reinforced concrete flat slabs in an actual building, hence his statement that credit was due to him. If this is not the case, credit is due to somebody else for it, *palmam, qui meruit, ferat.* No matter who it is, it is not of any consequence in connection with the point of the discussion, the distribution of bending moments in flat slabs.

V. J. ELMONT,

Montreal, November 17th, 1913.

A general survey of the mineral production of Canada for 1912 has been issued by the Department of Mines in the Dominion Government. The total value of last year's output, the greatest yet on record, was $135,048,296. This is an increase on 1911 of $31,827,302. Since 1886 mineral production has risen from $2.23 to about $19 per capita. Ontario leads the list with a production of $51,985,000, British Columbia comes second with $30,000,000, and Nova Scotia third with $18,922,000. A substantial increase in the price of most metals was a feature of the year, as was the extended development of ore reserves, pointing to much greater annual outputs in the future. Coal has been the most important product in point of value with a total production of $36,019,044; silver coming next in importance and nickel, copper and gold following. With the exception of petroleum every important mineral mined in Canada showed an increased production in 1912.

SOME NOTES ON HIGH RAILWAY ABUTMENTS.

By Alan Fraser, B.A.Sc.,
Assistant Engineer, Frank Barber, Toronto.

THE bridge seat of railway bridges is often high above water level or above the elevation of some similar obstacle to be crossed, such as another railway track or a highway. Therefore, occasions may frequently arise wherein the back fill or embankment supporting the track may be allowed to fall in front of the abutment shown by the *RD* in Fig. 1. This does not necessarily mean that the fill may come into contact with the surface of the bridge seat, such a condition being, to say the least, bad practice, and is in most cases not permissible. Attention is called to this fact in order to more fully appreciate the following, it being sufficient to state that the back fill should not, under any conditions, encroach upon the bridge seat.

With this in view the following points should be kept in mind when designing:—

(1) With a ballast wall on top.

(2) Angle between back of ballast wall and vertical axis, designated by θ.

(3) Angle of repose of the back fill.

(4) Distance from top of ballast wall to the bridge seat, designated by *S*.

A little thought will convince the reader that, other things being equal, the solution of the problem of keeping the back fill away from the bridge seat becomes easier as the angle of repose of the back fill increases. The ballast wall is, generally speaking, that part of the abutment immediately above the bottom of the bridge seat.

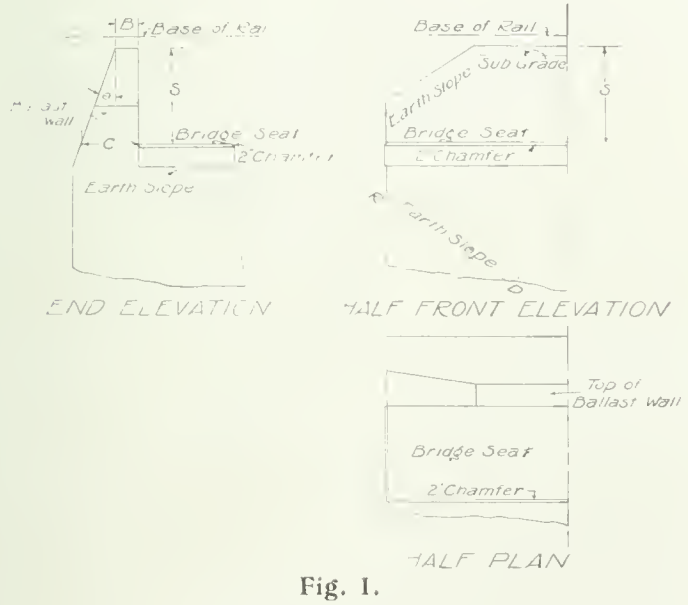

Fig. 1.

The frost batter is merely the slope on the back of the ballast wall.

Where, in Fig. 1,

B = width at top of ballast wall,

S = distance from top of ballast wall to the bridge seat,

θ = angle between back of ballast wall and the vertical axis,

C = width of the ballast wall in the same horizontal plane as the bridge seat.

Then, $C = B + S \tan \theta$ thus giving an empirical method for obtaining the thickness of the ballast wall in the plane of the bridge seat.

As the distance, *S*, becomes greater the problem of keeping the back fill away from the bridge seat increases in difficulty where wing walls are dispensed with. Where *S* becomes as high as eight feet, walls known as "lug walls" are used. These project left and right from the ballast wall. They are simply a continuation of the ballast wall and are shown in Fig. 2. It may be well to mention here that *S* increases in direct proportion to the increase of the span of which the bridge seat is an end support. The lug walls are developed to withstand as much of the

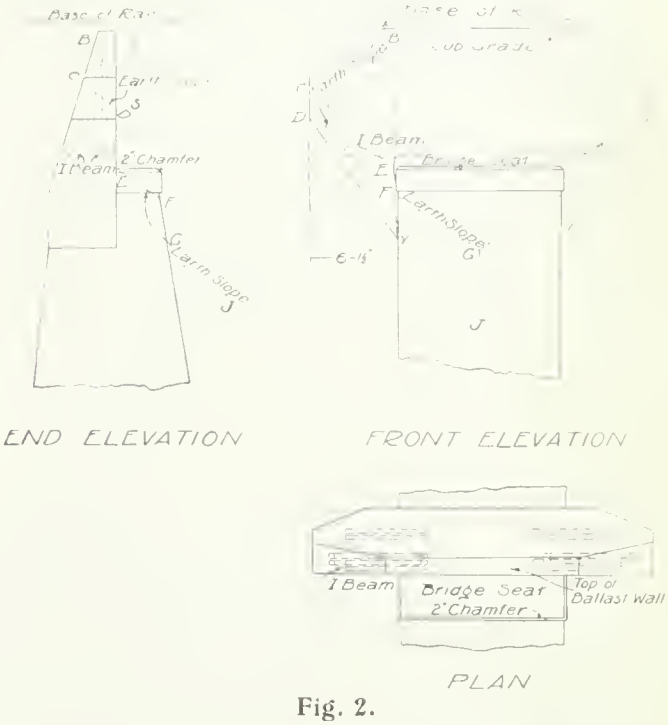

Fig. 2.

tendency to break off along the line *x y* as possible. It is not uncommon to use old rails or small I-beams as a reinforcement for these lug walls. The trained engineer need not be informed that the webs of I-beams should be in the vertical plane, so that the webs take up as much of the shear through *x y* as possible. The reinforcement of the projecting lugs is placed as economically as good practice will permit. The webs of I-beams, when used, may be assumed to take up all the shear that the concrete cannot resist, and this excess of shear is assumed to be distributed evenly over the webs. The reinforcement should be placed as near the back fill as possible, so that any tendency the back fill may have to snap off the projecting parts is, to a certain extent, overcome.

There is, of course, a limit to the safe projection of the lug walls. If beyond 5 or 6 feet, it may be expected that great difficulty will be experienced in their construction. The cost of the lug walls and the tendency (in spite of reinforcement) for them to break off becomes excessive. The attention of the reader is called to an article in October 23rd, 1913, issue of the "Engineering News," which treats with this type of abutment.

Where the depth *S* becomes over 12 feet (approximately one-tenth of the span) a patented design (No. 150003) obtained in August, 1913, by the writer, overcomes the problem of designing an economical, safe and easily constructed abutment without wing walls. This is shown in Fig. 3. The lines designated KL, LM, MN,

NO, OP, PQ correspond with the surface of the back fill during its fall from K to Q. The back fill will be observed to leave the bridge seat entirely free from encroachment.

Comparing this design with that shown in Fig. 2, where BC, CD, DE, EF, FG shows the surface of the back fill during its slope from B to G it will be observed that a considerable amount of concrete is saved. For a 120′ 0″ span the use of the abutment shown in Fig. 3 means a saving of approximately eight to ten yards both for single and double track lines. The fact that the projecting lugs in Fig. 2 are reduced from 6′ 1½″ to 2′ 6″ in Fig. 3, is sufficient to prove that the chances of their breaking off are much less than were they as long as would be the case were the design shown in Fig. 2 used in the place of the design shown in Fig. 3. Lastly, the construction is obviously easier.

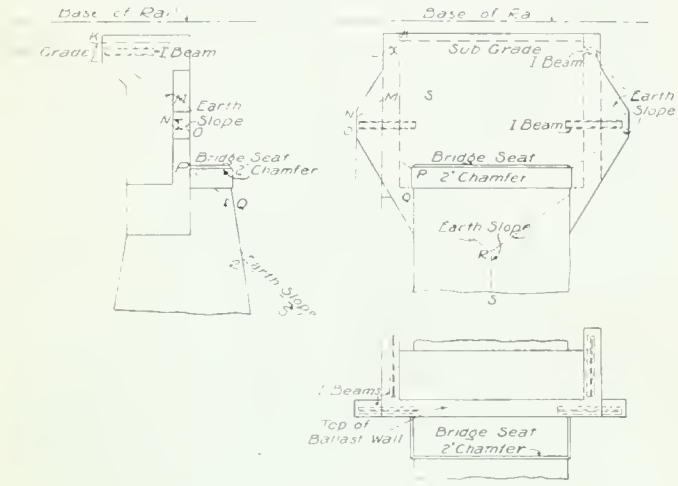

Fig. 3.

In order to keep the earth away from the bridge seat, it would, of course, be theoretically possible to reduce the length of the lug walls by constructing small curtain walls at both ends of the bridge seat. If this were done, however, the curtain walls would form a trap, as it were, between themselves and the steel deck girders. In this receptacle, however, the ice and snow collected during the winter would melt in the spring and tend to rust out the bed plates. Furthermore, there is a possibility of these curtain walls being destroyed during the erection of the steel work. In one case that the writer has observed, huge vertical columns of solid concrete were used to support the greatly extending and unsupported lug walls. The saving in concrete due to the absence of wing walls became almost a negative quantity.

Transcona Board of Trade is advocating a "good roads day," in which citizens of Transcona and those of Winnipeg (whose interests are more or less directly concerned in the building of an improved road to connect the two places) will be expected to turn out to make a good highway from Winnipeg to Transcona.

Railroads covering nearly a billion locomotive miles are in the competition for the first award of the E. H. Harriman Memorial Medals, which will be made at the First International Exposition of Safety and Sanitation, to be held in New York City, December 11th to 20th, under the auspices of the American Museum of Safety.

FIXED CARBON TEST.

"THE Fixed Carbon Test, designed for coal, has practically nothing to do with the finished quality of a refined asphalt, asphalt cement or road binder. It is a brand-identifying test."

The above extract from an article which he recently wrote, clearly indicates the opinions on the fixed carbon test that are held by J. W. Howard, C.E., E.M., of New York, whose work as a consulting engineering-chemist has been chiefly notable in the bituminous field. Col. Howard discusses the value of the fixed carbon test in more detail in the following letter:—

"The question has often been asked by city and state engineers, as well as many producers of excellent asphalt and bituminous cements and road binders, what, if anything, has the 'fixed carbon test' to do with the quality of these products for pavement and road construction? The answer is that it has nothing to do with the qualities of these materials. Fixed carbon is not a definite substance nor quality in any given coal or other material. It constitutes the results of an arbitrary test of the approximate portion of coal, which will remain and continue to burn and give heat after relatively light, volatile hydrocarbons have been partially burned away by flame. This test was devised solely for coal, by the committee on coal analysis of the American Chemical Society, and published in the Journal of the American Chemical Society, 1899, No. 21, p. 1116.

"The test is made briefly as follows: One gram of coal is put in a 'platinum crucible weighing 20 or 30 grams and having a tightly fitting cover. Heat over the full flame of a Bunsen burner for seven minutes. The crucible should be supported on a platinum triangle with the bottom 6 to 8 cm. above the top of the burner. The flame should be fully 20 cm. high when burning free, and the determination should be made in a place free from drafts. The upper surface of the cover should burn clear, but the under surface should remain covered with carbon.'

"It is therefore evident that the fixed carbon test has nothing to do with the quality or uses of asphalt, bitumens, asphalt cements and road binders. Burning and consequent destruction of the asphalt or bitumen proves nothing concerning the original condition and qualities before being burned. The qualities of the asphalt or other bitumens as used (not the burned products) are what are needed for cementing together and waterproofing the other materials in a pavement or road.

"No two persons, in the same or different places, with the various allowed sizes of crucibles, different sized Bunsen heaters, different kinds and pressures of gas, different lengths and sizes of flames, different distances the crucibles stand above the burner, even aside from the personal factor or difference in the way different persons work, can get the same quantity of fixed carbon (ashed free) or otherwise from the same sample of coal or other substance. When this variable process is applied to an asphalt or bituminous substance, even more widely varying and discordant results are obtained. It cannot be used as a basis of comparison of asphalt and bituminous materials, nor as a proof of their good or bad qualities.

"The attempted introduction of the fixed carbon test for coal into the asphalt industry has nothing to do with the determination of quality; nor can any minimum or maximum amount be set for this alleged test, between which all good asphalts and bitumens will come. Some good ones will be outside such limits, and some poor, worthless asphalts and bitumens will be inside any limits

attempted to be established by fixed carbon requirements. This test is sometimes used by chemists simply as a small but imperfect indication, taken with other special chemical tests, to identify, if desired, an unknown or unnamed brand of asphalt, but has nothing to do with quality. This test should not be placed among the tests for quality of asphalt, nor any road building materials.

"The fixed carbon (coal test) should be ignored if still found in asphalt or bituminous specifications, and not enforced, not only on engineering, but also on legal grounds, that 'the test does not apply to or establish any quality of the material necessary for the construction made or to be made,' i.e., in this case it does not apply to refined asphalt, asphalt or bituminous cement or road binder for constructing and waterproofing roads or pavements."

Col. Howard admits that a great deal of chemical and physical research work is necessary and useful to those who obtain crude materials and manufacture refined asphalts, road binders, etc., but he claims that research tests should not appear in specifications for pavements and road construction. He includes the fixed carbon test among the purely laboratory tests which do not apply directly to the quality of finished asphalt products and which, he says, are now best omitted from specifications.

"The determination of the amount of hydrogen, carbon and other ultimate elements of asphalt is interesting as a scientific study," says Col. Howard, "and bear somewhat upon the commercial and engineering problems connected with the sources of supply and manufacture, but have no place in contracts and specifications. Standard methods of making the tests to establish the requisite qualities (of asphalt, etc.) are found in various publications of the American Society for Municipal Improvements, the American Society for Testing Materials, the reports of the Association for Standardizing Paving Specifications, and in various other publications.

"A set of 'Standard Tests for Asphalt Cements for Sheet Asphalt Pavement' with numerical requirements or standards, prepared by the writer, will be found in the proceedings of the American Society for Municipal Improvements for 1911. A few of them are no longer needed for specifications but were inserted to check or confirm some of the other tests. The requisite qualities which good asphalt cements and road binders should possess are found in many products made from crude materials coming from California and other parts of the United States, from Mexico, Cuba, Trinidad, Venezuela and elsewhere, all of which asphalt cements and road binders are in successful use everywhere."

In the introduction to an article that appeared in Engineering Record recently, Col. Howard said: "The city, county, state and independent users are not concerned in the geographical source or crude materials from which asphalt products are manufactured. Specifications should have no requirements regarding the source of supply or the crude materials, nor the manner by which they are made into asphalt products. That is solely a matter for the manufacturers. Contracts should specify the qualities and tests needed for good asphalt cements or binders for use in pavement surface layers, just as they specify the qualities and tests needed for good Portland cements for use in foundations.

"Objectionable specifications which 'let in' or 'exclude' one or another asphalt, with few real quality tests, have lately been used for some highways. This is done by inserting irrelevant or useless tests for gravity, fixed carbon, paraffine, sulphur, etc., with special requirements or limits which fit the peculiarities of certain limited asphalt products, to the exclusion of others equally as good or better. Standard, essential, and useful tests are partly included and partly omitted, according to whether or not the asphalt product, thus secretly described (except to an expert), meets good requirements or not. Such wrong, unwise, and unjust specifications are being steadily eliminated by good men."

Readers who noted Mr. Pullar's suggestions of methods for making the fixed carbon test of increased value, which appeared in the Nov. 13th issue of *The Canadian Engineer*, and those also of Mr. Law, appearing in last week's issue, will notice the marked difference of opinion between Col. Howard and Mr. Law on one side and Mr. Pullar with an opposite view as to the value of the fixed carbon test; although all three evidently think that it is useless to write a specification naming the same maximum limit for fixed carbon for all asphalts.

The difference of opinion on this subject between these writers is indicative of the doubt that exists at the present time among municipal and highway engineers as to whether the fixed carbon test has properly a place in their specifications for asphalt supply. *The Canadian Engineer* invites letters from any engineers who may have well-defined views on this subject.

HIGHWAY ENGINEERING AT COLUMBIA.

The non-resident lecturers in the Graduate Course in Highway Engineering at Columbia University appointed for the 1913-1914 session are as follows: John A Bensel, New York State Engineer; William H. Connell, Chief, Bureau of Highways and Street Cleaning, Philadelphia; C. A. Crane, Secretary, the General Contractors' Association; W. W. Crosby, Chief Engineer, Maryland Geological and Economic Survey, and Consulting Engineer; Charles Henry Davis, President, National Highways Association; John H. Delaney, Commissioner, New York State Department of Efficiency and Economy; A. W. Dow, Chemical and Consulting Paving Engineer; H. W. Durham, Chief Engineer of Highways, Borough of Manhattan, New York City; C. N. Forrest, Chief Chemist, New York Testing Laboratory; Walter H. Fulweiler, Chief Chemist, United Gas Improvement Company; Frank B. Gilbreth, Consulting Engineer; George P. Hemstreet, Superintendent, the Hastings Pavement Company; Samuel Hill, President, American Road Builders' Association; D. L. Hough, President, the United Engineering and Contracting Company; J. W. Howard, Consulting Engineer; Arthur N. Johnson, State Highway Engineer of Illinois; William H. Kershaw, Manager, Paving and Roads Division, the Texas Company; Nelson P. Lewis, Chief Engineer, Board of Estimate and Apportionment; New York City; Harold Parker, First Vice-President, Hassam Paving Company; Paul D. Sargent, Chief Engineer, Maine State Highway Commission; Philip P. Sharples, Chief Chemist, Barrett Manufacturing Company; Francis P. Smith, Chemical and Consulting Paving Engineer; Albert Sommer, Consulting Chemist; George W. Tillson, Consulting Engineer to the President of the Borough of Brooklyn, New York City.

Electric blasting is being employed in certain mines in South Africa. The whole of the one level at a leading mine was fired recently by the new system. There were 300 shots in the blast, which was effected from a station, only one man being required below for the firing. Cables are now placed to enable blasting to be effected from the surface. The system so far has proven satisfactory.

TORONTO FILTER SPECIFICATIONS

BOARD OF CONTROL AUTHORIZES CALL FOR TENDERS FOR MECHANICAL PLANT OF SEVENTY-TWO MILLION IMPERIAL GALLONS DAILY CAPACITY —RESUMÉ OF ESSENTIAL PARTS OF CITY ENGINEER'S SPECIFICATIONS

TORONTO'S Board of Control yesterday gave formal permission to Commissioner of Works R. C. Harris to advertise for tenders for a complete mechanical filtration plant at Toronto Island, the plant to include pumping station, chemical storage room, coal storage building, filter house, mixing tanks, coagulating basins, clear water basins, filter units with complete equipment, crane, pumps, valves, boilers, chimney, turbo-generator set and all appurtenances.

The estimated cost is approximately one million dollars. The specifications require that work shall be commenced within ten days after the execution of the contract, and shall be carried on without delay, so that one-half of the filter plant and all its accessories shall be in satisfactory service not later than December 31st, 1914. A bonus of one hundred dollars a day is offered for completion of the first half of the plant earlier than that date, and a penalty of two hundred dollars a day is imposed for non-completion of the first half of the plant by that date. Should the plant not be completed within sixty days after December 31st, 1914, the penalty then increases to three hundred dollars a day.

It is also required that the whole filter plant shall be completed and operating satisfactorily not later than September 30th, 1915, and a penalty of fifty dollars a day is imposed for delay beyond that date, allowances in every case, of course, being made for delays caused by strikes, or by any act of the City Council, or on account of additional work ordered, or for any other delay for which, in the opinion of the Commissioner of Works, the contractor cannot be held responsible.

"It is the purport of these specifications and also of the instructions to tenderers to obtain bids for a plant which will be first-class in every respect and equal to the best on this continent, and complete in every detail, and ready to operate." This sentence in the specifications expresses the spirit in which the Works Department is regarding this plant. The Commissioner of Works and Engineers Powell, Milne and Barr, who have all done notable research work in gathering data for the preparation of the specifications for this plant, are determined that Toronto shall have a filtration plant that will not be outranked by any on this continent, and in the specifications they have guarded the plant, seemingly, in every possible way.

Specifications Ensure Good Plant.

It is the intent of the specification to permit bids to be submitted by the proprietors and licensees of any mechanical filter, provided they comply with the guarantees and duties required by the specifications. Yet, the provisions made regarding guarantees, bond and surety regulations are such as to ensure the city's receiving bids only from firms who are financially responsible and who have absolute faith in their ability to live up to the guarantees required.

A marked cheque or cash deposit is required for the sum of two and one-half per cent. of the value of the tender. A satisfactory bond must be furnished to the full extent of the contract price for the proper performance of the work, and in addition to this a bond will be required for five years from date of acceptance of the completed plant by the city, for the cost of the foundations, substructures, superstructures and chimney, in order to guarantee their not failing. This is on account of the sand on which they must be built. Similarly, all machinery, equipment and appurtenances must be guaranteed free from all visible or inherent defects for one year from date of acceptance. Eighty per cent. of the value of the work done and materials incorporated in the work will be paid monthly by the city. One year from the date on which all tests as to efficiency and capacity have been made, and the plant and all its accessories accepted as satisfactory to the Commissioner of Works, the remaining twenty per cent. will be paid. Payments may be withheld at any time if the work is not proceeding in accordance with the contract.

Besides being protected by the heavy guarantees required and the general rigid and high character of the entire specification in all details, the plant's success is further guarded by the requirements imposed regarding responsibility and reliability of the contractors. The specification says:—

"Bidders must furnish satisfactory evidence of their experience and ability to construct this class of work, and that they have construction and financial resources to enable them to prosecute the same successfully and promptly, and to complete the work within the time named in the contract. Evidence must be submitted showing positively that the tenderer has designed or constructed similar work."

Strainer System Must Be Perfect.

All modern appliances are specified under the heading of "filter equipment," and special attention is given to the strainer system. The specification says that while it is not the intention to limit the tenderers to any particular type of strainer system, it must be distinctly understood that anything in the nature of an experiment will be prohibited. Should tenders cover any design that has not been in successful operation for at least three years, the city will require a bond for the sum of seventy-five thousand dollars for the proper maintenance of such a type of strainer system for a period of five years after the completion of the plant.

Tenders must be mailed by registered post and will be received up to noon, January 20th, 1914. The Works Department will examine and compare the various tenders and expect to award the contract about three weeks after receipt of tenders. Each tenderer will be required to submit a full set of plans drawn to scale, showing the general arrangement of the plant in relation to the existing slow-sand plant and connection thereto, also showing the position of the pump room, coagulating basin, filters, etc. There drawings must show in detail the entire plant. In other words, they must be descriptive of the system by which the tenderer expects to live up to the guarantees required in the specification. Two months after the award of the contract, the successful tenderer must furnish in

duplicate accurate drawings showing all parts of the plant in such detail that the whole may be erected from those plans.

While the city specifies that the plant must be "mechanical," that is slow-sand designs are barred, the competition is open to all types of mechanical plants, whether pressure or gravity, patented or unpatented, provided, of course, that all guarantees required are furnished and all other conditions of the specifications complied with.

The specification is very complete, comprising eighty pages of printed matter, with an appendix giving a very useful index to contents. The language used is clear and concise, and the general arrangement of the specification lends itself to the easy finding of any particular portion.

As previously stated in *The Canadian Engineer*, the plant is to be capable of satisfactorily filtering continuously sixty million Imperial gallons every twenty-four hours, with a maximum capacity of not less than thirty million Imperial gallons during any ten hours. The effluent at all times is to be of the standard of purity required by the specifications. This, of course, practically means that the plant must have a daily capacity of seventy-two million Imperial gallons.

Pure Water Assured.

The contractor will be required to guarantee that the mechanical filtration plant which he proposes to furnish, will remove 90 per cent. of all organisms where there are 50 to 500 bacteria per cubic centimeter in the unfiltered water; will remove 95 per cent. of all organisms where there are 500 to 2,000 bacteria per cubic centimeter in the unfiltered water; and 98 per cent. of all organisms where there are 2,000 or more bacteria per cubic centimeter in the unfiltered water.

The contractor must also guarantee removal of 98 per cent. of the B. Coli as determined by the standard methods for the examination of water of the American Public Health Association. All turbidity must be removed, leaving a bright, colorless water, free from taste. Such results must be guaranteed by the use of not more than one grain of alum per Imperial gallon of water, under average conditions. Where such is required, a sedimentation period of not less than three hours must be provided for after the addition of alum.

Each tender must be accompanied by a report of some similar plant, municipal or otherwise, of at least one-half million gallons daily capacity, such report having been made by a reputable disinterested bacteriologist, and showing the daily bacteriological analyses of the water before and after filtration for a continuous period of at least thirty days, including the percentage of B. Coli organisms removed, as well as the percentage of the total number of bacteria; also showing the removal of suspended matter, and the nature of the effluent.

A schedule of quantities must be furnished, showing in detail the prices of the various classes of work and articles to be supplied, which make up the total tender price. These unit prices are for comparison only, and if the contractor finds he has underestimated quantities he can make no claim for extra remuneration, but must supply the additional quantities necessary to the work. The idea of obtaining unit prices is good, as it allows of much fairer comparison of tenders. A firm whose bulk tender is higher than another firm's may really be figuring on lower unit prices, but the higher firm's plans would then call for more material in the work. It would then remain for the Department of Works to determine whether the greater amount of material would add anything to the stability or efficiency of the plant; also whether the lower firm had made up their low bid by skimping quantities.

The Work Involves Difficulties.

The building of the plant involves engineering and contracting difficulties, and for that reason the specification requires all tenderers to visit the site of the plant, and to familiarize themselves with existing or future obstacles to speedy and safe construction. None of the material excavated from the foundations or otherwise, nor any of the material adjoining the filter plant, or on the Island, or under the waters in the vicinity of the Island, can be used in the construction of the work, without the express consent of the Works Commissioner. It is thought that this is to avoid a repetition of troubles encountered during the construction of the existing slow sand plant.

Tenderers must describe thoroughly the method that they propose to adopt in all the foundations required. The concrete work is well guarded by the specifications, which give instructions regarding materials to be used, the placing, setting and waterproofing of the concrete work. The mixtures to be used are to be satisfactory to the Works Commissioner. The contractor must provide reliable means for handling the water, which may prove troublesome in excavations at the Island, and he must not allow the water to rise above the lowest point to which he excavates. Duplicate machinery, if required, must be provided by the contractor, so that positive drainage is assured.

While it is the intention of the city to have wash-water pumps, air-blowers and other apparatus requiring small power units, operated by electrical motors, contractors are requested to put in an alternative bid for other drives for the three low-lift pumps required. Alternative No. 1 permits these low-lift pumps to be driven by vertical, compound or triple expansion condensing engines. Alternative No. 2 permits these low-lift pumps to be driven by gas engines or in any way desired by the tenderer. In deciding whether to substitute either of these alternatives for the electric drive, the Works Department will take into consideration the cost of transporting coal, etc., to the Island.

The contractor must state in his tender when one-half of the filter plant will be completed, and ready to operate, and when the filter plant as a whole will be completed and ready to operate. Should these dates of guaranteed completion be earlier than December 31st, 1914, and September 30th, 1915, respectively, that fact would undoubtedly be a point in favor of that tenderer. The reason that the Works Department is placing a bonus, as mentioned above, on the early completion of the first half of the plant is that they really need the thirty million gallons of filtered water that one-half of the new plant would give them daily. The existing slow sand plant is not filtering the full requirements of the city.

Must Live up to Guarantees.

The Medical Officer of Health is to test the plant for clarity of effluent and bacteriological efficiency within three months after the plant, or portion thereof, is placed in operation, and in the event of failure to fulfill the guarantees the entire plant may be rejected and all payments to the contractor recovered.

The whole of the work must be carried on and completed without interference with, or interruption of, the operation of the present slow sand plant. The contractor cannot assign, or sublet, any portion of the work without the consent of the Works Commissioner.

The specification includes, of course, all the usual clauses regarding tests, workmen's rights, progress certificates, inspectors' powers, etc., but the following points covered by the specification may be interesting to engineers and contractors interested in water supply problems:—

It is the intention to utilize the present clear water reservoir, which has an area of 2.2 acres with a depth of 12 ft., but it is probable that some bidders may require a clear water basin. If so, cost of same must be included in tender. The work also includes:—

The necessary number of mechanical filter units of four million Imperial gallons each, or approved equivalent. These units to be complete with all appurtenances. Filters will be grouped on both sides of the piping gallery, which will be utilized as an operating platform. Filter tanks to be of steel or reinforced concrete. Filters to discharge into clear water reservoir at Elevation 45, Toronto datum.

The low lift pumping machinery shall comprise three centrifugal pumping units, each of not less than 36,000,000 Imperial gallons capacity per 24 hours. Units to be capable of pumping from an elevation of 30 (Toronto datum) to whatever height is necessary for delivering the water to the filters.

The necessary wash water pumps connected to the tank. Each pump shall be of ample capacity to supply all the wash water required for the entire plant.

The necessary air-blowers, each of which shall be of ample capacity to supply all the air required at the desired pressure for washing.

Interesting Specification Details.

All piping and connections from shore end of existing intakes to pumps, including hydraulically operated valves, together with well and surge overflow, all furnished and erected in place.

The amount specified by tenderer for coal storage shall provide for a building capable of storing not less than 1,500 tons of coal, and shall include coal-handling apparatus from scow to storage building, and from thence to boiler-room.

The low lift pumping station shall be of ample size and proper construction to accommodate all the apparatus requisite for pumping the water, together with the wash water pumps, air-blowers, travelling crane and other machinery, and also to accommodate certain enumerated machinery that will be moved from the old to the new pumping station, as the old station is crowded.

The window frames and sash of all buildings shall be of approved pressed steel, fitted with first quality wired glass.

All plans and specifications submitted by the tenderers shall become the property of the city, and must be specially prepared for this work, and be in sufficient detail so that the quantities of the work and materials can be computed with accuracy.

The contractor shall furnish and install all the necessary filter equipment, including strainer system, filter piping, the necessary hydraulically operated valves, all the operating tables, loss of head gauges, air and wash-water gauges, recording gauges for wash-water tank, measuring apparatus for automatically recording the amount of wash water used, filter sand, filter gravel, rate controllers, wash-water pump and gutters, air-blower with requisite motive power, sampling devices, water meters.

Tenderers may also tender on a combined air and water wash, consisting in the application of both compressed air and filtered water through the strainer system.

Tenderers may bid on a separate air and water wash, comprising the application of compressed air through a separate air-distributing system of perforated brass tubes and of the filtered water through the strainer system.

The general design of the strainer system shall be such, that in combination with other parts of the filters and filter piping a uniform distribution of wash water and of air, if used, shall be ensured over the entire bottom of the filters; it shall be designed so as to completely drain the bottom of the filters; the system shall be substantial, and provision made that the parts may be readily renewed. Further, the individual openings in the system shall be large enough so as not to be easily clogged, and yet small enough and so formed as to secure uniform distribution of the wash water.

Operating Equipment Complete.

The contractor shall furnish and install on each operating table a loss-of-head gauge of approved type, complete with all the necessary floats, float tube, counterweight, wire, pulleys and other appurtenances. The gauge shall be arranged to accurately record the loss of head through the corresponding filter by means of an approved pen upon a chart mounted on a disk or drum revolving once in twenty-four hours, graduated in an approved manner, so as to report distinctly losses ranging from zero to the maximum, while the travel of the pen is about 6 inches. The float tubes shall be 8-inch galvanized wrought iron pipe of ample length, capped at the lower end, and securely fastened in a truly vertical position. Floats shall be seamless and spherical, about 6-inch diameter, and made of copper. The connections from the filters and effluent pipe shall be of not less than ¾-inch brass pipe, with brass nipple, through the wall of the filter.

Provision must be made to prevent the entrance of wash water or sand into the float tubes. The mechanism of the gauge shall be of brass enclosed in a strong, neatly finished, heavily nickel-plated brass case, same to be accessible for adjustment and repair. Connection shall be made to the tubes to permit of adjustment and drainage, and valves shall be placed on the connections between the tubes and the filter wall or effluent line respectively.

Special care shall be taken in transporting and placing filter sand to prevent contamination of any sort, and sand which may have become dirty, either before or after placing in the filters, shall be washed or removed or replaced by clean sand in a satisfactory manner. All contaminated sand shall be rejected. After sand is in place in the filters it shall be washed at least ten times with the washing devices connected with the filter, and the fine sand appearing at the surface shall be removed by scraping or otherwise. Sufficient sand shall be placed in each filter bed to secure a layer of the proper depth required for giving the most efficient results after the sand has been washed and scraped. The contractor must state the depth of filtering medium in inches required in the filters, and he must also state the effective filtering surface, and the rate of filtration in Imperial gallons per sq. ft. per hour.

The contractor shall furnish and erect in suitable location, approved by the Commissioner, one chimney not less than 120 feet in height above the grate bar level, with an inside diameter not less than 84 in. This chimney may be built of buff brick or other approved material, and provided with stranded copper lighting conductor, with all necessary ground and other connections, and of design approved by the Works Commissioner.

BOOK REVIEWS.

GRAPHICS AND STRUCTURAL DESIGN.—By H. D. Hess, M.E., Professor of Machine Design, Sibley College, Cornell University. New York: Publishers, John Wiley & Sons, Inc., London; Canadian selling agents, Renouf Publishing Company, Montreal; pp. viii. + 426; 361 text figures; cloth; 6 x 9 inches. Price, $3.00 net.

Reviewed by C. R. Young, M. Can. Soc. C E.,
Assistant Professor of Structural Engineering, University of Toronto.

In spite of the frequent condemnation of general treatises on structural engineering, there exists a considerable demand for such works. Many engineers, whose activities lie mainly outside the structural field, as well as those just entering it, feel the need of a simple, elementary, immediately-usable book on the design of a variety of ordinary, everyday structures. Numerous attempts to meet this demand have been made, and it must be admitted that they have not always been attended with success. Inadequate and erroneous treatment of the subjects discussed, with the complete neglect of others equally important, has so frequently characterized such efforts that the chances of the reader deriving any real assistance from a book of this kind purchased at random are small, indeed.

The present volume is an unusually successful venture in this difficult field. The author's special object is the discussion of useful problems "on the border line between Civil and Mechanical Engineering," and, while the book is intended for student use, it cannot fail to be of very real value to any one whose work is not too highly specialized.

Of necessity, many subjects must be treated in the borderland which Professor Hess indicates as the field of his book. The subject is introduced by the presentation in the first chapter of general data on materials, common formulas and properties of sections. Chapters 2 to 5 are devoted to graphical and analytical methods of analysis of structures, including the method of influences diagrams. Chapter 6 concerns riveted connections. Columns are given an effective short treatment in Chapter 7. A variety of steel structures are then given consideration, covering conveyer girders, trussed and suspended pipes, transmission line towers, mill buildings, a railway girder span, crane frames and bridges of travelling cranes. Unfortunately, no attempt is made at stress analysis in the case of transmission line towers, although a few pages on this subject would have supplied a very real present need in engineering literature. The author's reason for designing a railway plate girder was that it made a more comprehensive and better problem than a runway girder, and one who could design the former was well prepared for the simpler structure. A particularly useful portion of the book is the 28 pages devoted to the detailed design of the structural parts of jib and travelling cranes. In reinforced concrete, slabs, beams and columns are covered in a concise manner. Foundations, including those for machines, form the subject of Chapter 15. A very valuable chapter is that on chimneys, comprising the design of these structures in brick, steel and reinforced concrete. Chapter 17 contains a discussion of retaining walls, with a detailed design of a typical wall, while Chapter 18 is given to the consideration of the allied subject of bins. Floors, walls and roofs occupy Chapters 20 and 21. One of the most valuable features of the book is the inclusion of authoritative specifications covering materials, design and workmanship in both steel and reinforced concrete structures, and such clauses as are necessary to cover the timber and masonry work entering into ordinary structures. The volume is concluded with 195 useful problems.

One does not find it difficult to commend the book. Indeed, every mechanical engineer who has to do with structural problems at all, and every civil engineer who must at times concern himself with the structural features of the mechanical engineer's work should possess a copy.

Overhead Electric Power Transmission.—By Alfred Still. Published by McGraw-Hill Book Company, New York. 306 pages; illustrated; cloth; 6 x 9 inches. Price, $3.00 net.

Reviewed by Prof. H. W. Price,
Department of Electrical Engineering, University of Toronto.

Books have been published which deal copiously with problems of engineers in charge of construction of lines for high and low voltage and of moderate and large capacity. Other books treat the complicated problems of high-voltage, long-distance transmission. This book by Mr. Alfred Still is aimed directly at a composite field, of special value and convenience to engineers having under consideration the design of a transmission system for estimated service.

Three outstanding features of this book are these: (1) It is evidently written by a man who has been "through the mill," and has known the inconvenience of searching here and there for specific information on methods of arriving at the best choice of details of a transmission system for given service under specified operating and financial limitations. The book resembles the notes of such a man, who took time to systematically arrange and elaborate the problems he considered, and examples of his methods of solution.

(2) The information contained is thoroughly cross-indexed for convenience of the reader. An unusual supplementary index of formulas, data, charts, sample calculations,

etc., is provided for convenience of those actually engaged on transmission line calculations.

(3) This book does not assume to be the only competent source of information on the subject treated. As any proper engineering book should, it contains numerous footnotes and references advising the reader of authorities and further information on points in question.

Transmission lines are considered from many points of view: Economic choice of system, of spans, conductors, flexible and solid towers, insulators, protective devices, etc., etc. Considerable space is given to a method of applying Kelvin's Law to collected data to determine the features of system to yield maximum economy. A brief is given of the latest information on high-voltage, high-frequency disturbances and their effect on line and connected apparatus. High-voltage, direct-current transmission receives some attention. A sample set of specifications for a transmission line is included, which the author hopes will be of service, in that it may suggest points to be covered which might otherwise be overlooked.

Switchgear and the Control of Electric Light and Power Circuits.—By A. G. Collis, A.M.I.E.E. Constable & Company, Limited, London, W.C. 82 pages; 46 illustrations; cloth; 4 x 7 inches. Price, 30 cents net.

Reviewed by A. S. L. Barnes,
Hydro-Electric Power Commission, Toronto.

This is a book of 82 pages, forming one of a series, called "Electrical Installation Manuals," which is being put forward by the publishers.

The best feature of the book is its insistence on simplicity in the design and arrangement of switchgear.

Many diagrams of connections for all kinds of service are given. Some of these are good, but several of them are very difficult to read, and in one or two cases it is hardly possible to do so at all, this being partly due to the author's having attempted to include rather too much detail, partly because, to indicate various types of apparatus, he has employed symbols that are not very generally used. Again, in some cases the diagrams are surrounded by marginal lines which are badly confused with the lines of the diagrams. In one figure a dynamo appears to be short-circuited, and in another a shunted ammeter is mysteriously connected across the main bus bars—unless, perchance, these two extra lines are intended to supply current to a lamp at the back of the instrument, which appears to be of the illuminated dial pattern!

The book is not one which, in its present form, is likely to make much of a mark for itself, although its usefulness might be much improved by a careful revision of the diagrams in order to make them more intelligible.

General Metallurgy.—By H. O. Hofman, E.M., Metallurgical Engineer, Ph.D. Professor of Metallurgy, Massachusetts Institute of Technology. Published by McGraw-Hill Book Company, New York City. 909 pages; 836 illustrations; 252 tables; numerous inserts of plates; cloth; size, 6 x 9 inches. Price, $6.00 net.

Reviewed by T. R. Loudon, B.A.Sc.

As stated in the Preface, it is the object of this book "to cover the field of General Metallurgy." There are, of course, certain principles common to the various fields of metallurgical endeavor, and it is to the expounding of these principles that this book is given over. The book is very well written and the illustrations are good. As to the value of such a work portions are appropriate as a reference for the advanced metallurgist and other sections will be of value to the beginner. In most books covering a wide field of scientific work, there must necessarily be many sections of reading matter that are not truly explanatory, but are mere statements of fact. For this reason the value of such books is often doubtful, as the beginner requires above all things, clear explanations; and, on the other hand, the advanced reader already knows the facts. It must be said, though, that the amount of explanatory matter given in this book is in a very good proportion to the amount of mere statement of fact. One very noticeable feature about the book that is good is the enormous number of references given. The author has certainly spent a great deal of time on the work of gathering together a list of references that in themselves constitute a very valuable addition to metallurgical literature.

There are thirteen chapters to the book, the titles to which are as follows: Introduction; Properties of Metals; Alloys; Metallic Compounds; Ores; Fuel; Refractory Materials; Pyrometallurgical Processes and Apparatus; Hydrometallurgical Processes and Apparatus; Electrometallurgical Processes and Apparatus; Mechanical Metallurgical Operations, a chapter which is subdivided into sections dealing with Ores, Metal Alloys, Liquids, Gases, Preheating and Drying of Air, Purification of Gases; Metallurgical Products; and Economic Considerations.

The chapter on Mechanical Metallurgical Operations is very well put together, and, on account of its large amount of illustrated explanatory matter, is a valuable general reference. On the other hand, such a chapter as that on Electrometallurgical Processes and Apparatus, while it does contain certain laws that apply in Electrometallurgy, is so fragmentary that it is difficult to see just where its value lies. The chapter on Refractory Materials is very good.

As stated before, the book is a valuable addition to Metallurgical literature if for no other reason than the references given in connection with the written matter.

PUBLICATIONS RECEIVED.

The Approximate Melting Points of Some Commercial Copper Alloys.—10-page leaflet, issued under authority of the United States Bureau of Mines, by H. W. Gillett and A. B. Norton.

Mine-Accident Prevention at Lake Superior Iron Mines.—A 38-page bulletin, compiled by Dwight E. Woodbridge and issued by the United States Bureau of Mines, dealing with mine-safety problems.

Coal Mining Disputes on Vancouver Island.—40-page report of the Royal Commissioner on coal mining disputes on Vancouver Island. Issued with the authority of the Minister of Labor, by Samuel Price.

Problems in Physics.—23-page leaflet, based upon the Text-Book of Physics, by A. Wilmer Duff (editor), etc. Issued by Morton Masins, Ph.D., of the Department of Physics, Worcester Polytechnic Institute, Worcester, Mass.

Uses of Commercial Woods of the United States.—56-page bulletin, No. 12, published by the United States Department of Agriculture. Written by Hu Maxwell, expert, and dealing principally with beech, birches, and maples, as commercial woods of the United States.

Vitrified Brick as a Paving Material for Country Roads.—34-page illustrated bulletin, No. 23, authorized by the United States Department of Agriculture, and edited by Vernon M. Peirce, Chief Engineer, and Charles H. Moorefield, Senior Highway Engineer, office of Public Roads.

First Aid Instructions for Miners.—A 66-page bulletin, compiled by M. W. Glasgow, W. A. Raudenbush and C. O. Roberts. It is well illustrated, and serves as a guide to

miners in rendering aid to injured fellow-workmen. Issued by the Bureau of Mines, Department of the Interior, Canada.

Tide Tables for the Pacific Coast.—By W. Bell Dawson, Superintendent, Tidal and Current Survey, Department of Naval Service, Canada. The Bulletin gives complete tide tables for the year 1914, and includes Fuca Strait, the Strait of Georgia and the Northern Coast. It also contains data for Slack Water in the navigable passes and narrows, with information on currents.

Tide Tables for the Eastern Coasts of Canada.—By W. Bell Dawson, Superintendent of the Tide and Current Survey in the Department of the Naval Service of the Dominion of Canada. The bulletin gives complete tide tables for the year 1914, and includes the River and Gulf of St. Lawrence, the Atlantic Coast, the Bay of Fundy, Northumberland and Cabot Straits. It also contains information on currents.

Forest Products of Canada, 1912.—Bulletin No. 40, Forestry Branch, Department of the Interior, Canada, compiled by R. G. Lewis, B.Sc.F. The bulletin contains an account of the quantity of wood manufactured into lumber in the Dominion and the various provinces for the year 1912. Tables are also given showing the quantities and value of the different kinds of wood manufactured into lumber during the year specified.

Arguments for and Against Train Crew Legislation.—A 38-page bulletin, published by the Bureau of Railway Economics, Washington, D.C., dealing with the much-talked-of subject of the regulation of train crews, giving the history and present status of train operation, the provisions of the measures enacted and proposed for "full crew" legislation, and a discussion of the effect that such legislation would have upon the efficiency and safety of transportation.

Working of Steam Boilers.—147-page book, fifth edition, well illustrated, and indexed. Published for those in charge of, and responsible for, the working of steam boilers insured with "The National Boiler and Insurance Company," giving directions essential to safety, and also precautions necessary for satisfactory working and for the prevention of undue deterioration of the steam-raising plant. Issued by Edward G. Hiller, B.Sc., M.I.C.E., M.I. Mech. E., Chief Engineer, the National Boiler and General Insurance Company, Limited, Manchester, Eng.

Mines Statement, New Zealand, 1913.—7½ x 13 inches, well supplied with maps and illustrations, being the mines statement for the year ended the 31st December, 1912, and including statistics, reports relating to metalliferous mines and stone-quarries, state aid to mining, roads on goldfields, prospecting-drills, water-races, school of mines, inspection of mines, examinations for certificates, geological survey, state coal mines, diagrams, maps, and plans. The publication has been compiled by the Hon. W. Fraser, Minister of Mines for New Zealand, and covers approximately 160 closely-set pages.

Forest Protection in Canada, 1912.—164-page book, 7½ x 10 inches, well illustrated, and with map inserted. The publication is subdivided under six main topics, e.g., protection from railway fires; forest fires and the brush disposal problem; the top-lopping law in the Adirondacks; the use of oil as locomotive fuel from a fire-protective point of view; forest planting in Canada; report of committee on forests, Commission on Conservation, 1912. There are, moreover, three appendices—the first, concerning Dominion forest reserve extension in Manitoba, Saskatchewan, Alberta, and British Columbia, and a table of forest reserve areas; the second, memorandum regarding the country between Sudbury and Port Arthur, by J. H. White; the third, opinions on fuel oil.

The report is edited by Clyde Leavitt, Chief Forester of the Commission of Conservation, and Chief Fire Inspector of the Board of Railway Commissioners, and is issued by authority of the Dominion Government Commission of Conservation.

CATALOGUES RECEIVED.

National Metal Moulding.—A 28-page catalogue of mouldings, couplings, outlets, receptacles, bushings, flush-plates, etc., for sale by the Canadian General Electric Company of Toronto.

A Thousand Uses for Gas.—An 8-page well-illustrated catalogue dealing with gas and the various uses to which it may be put. Issued by the United Gas Improvement Company, Philadelphia, Pa.

Standard Class "NF-2" Compressor.—A leaflet descriptive of the important features governing air-compressor selection, and of the vital points of automatic operation. Published by the Canadian Ingersoll-Rand Company, Montreal.

Transformer Drying, and the drying, filtering and testing of transformer oil.—A 16-page bulletin, No. A4134, descriptive of the General Electric transformer dryer and filter. The Canadian General Electric Company, selling agents.

The Morrison Water-Tube Boiler.—A 10-page catalogue dealing with the water-tube boiler as a preventative of costly accidents and delays, the reduction of maintenance and repair expenses, etc. Issued by the Morrison Boiler Company, Sharon, Pa.

Electricity in Iron Foundries.—A Bulletin issued in October by the General Electric Company, descriptive of the electrical operation of cranes, air-compressors, elevating and conveying machinery, etc. The Canadian General Electric Company are the selling agents.

Chicago Pneumatic Corliss Compressors.—Bulletin No. 24D, issued by the Chicago Pneumatic Tool Company, descriptive of their horizontal, cross-compound Corliss compressor. It is well illustrated and furnished with tables of dimensions, and occupies 32 pages.

Improved Forced-Draught Furnace.—A 12-page, illustrated catalog descriptive of the "Meldrum" furnace; another describing their "Koker" and "Sprinkler" mechanical stokers, and a third dealing with refuse destructors. Issued by Meldrums, Limited, Manchester, Eng.

Rotating Hammer Drills.—A 12-page catalogue descriptive of the McKiernon-Terry rotating hammer drills for sinking, stoping and drifting; illustrated and including specifications, weights, etc. The Canadian Allis-Chalmers, Limited, Toronto, are the Canadian selling agents.

Cars, Tracks, Turntables, Switches, etc.—Catalogue No. 900 of the Orenstein-Arthur Koppel Company, Koppel, Pa., descriptive of their many products, comprising rails, portable track, switches, cars, turntables, steam and electric locomotives; well illustrated and tabled, comprising 84 pages. The Canadian Fairbanks-Morse Company are the Canadian sales agents.

Book Catalog.—A new illustrated catalog of scientific, industrial and technical books has been issued and will be mailed post-free by Crosby, Lockwood & Son, 7 Stationers Hall Court, London, England. Among the new books listed are an English and German Pocket Glossary of Technical Terms, and "Screw-Cutting for Engineers," a very practical book for mechanics.

Floating Docks.—A well-illustrated 50-page book descriptive of floating docks, published by Swan, Hunter & Wigham Richardson, Limited, Wallsend-on-Tyne, ship engine and floating dock builders and repairers. The booklet contains 50 illustrations of various docks and an article dealing with the subject in an interesting, descriptive constructional manner. It also contains a lengthy list of docks built by this company.

Willans Rotary Air-Pump System.—This is pamphlet No. 50, issued by Willans & Robinson, Limited, Victoria Works, Rugby, Eng., descriptive and illustrating the Muller-Josse patent rotary air-pump system, showing the two most common applications, viz., the shunt and series system. In either case the air is extracted from the condenser by means of an air-ejector, and the condensed steam extracted by means of a separate centrifugal pump drawing the water from the bottom of the condenser.

Robb's Scotch Boilers.—A Bulletin issued by the International Engineering Works, Limited, descriptive of the Robb Scotch marine boiler, showing changes from the standard design in the interests of better circulation, etc. The boiler is fully described in the bulletin, and details of a special economy test, in which the 200 h.p. boiler, operated a widely fluctuating load, showing an average of 73 per cent. efficiency when working under variable conditions up to 50 per cent. overload. The International Engineering Works, Limited, have sales offices, in Toronto, Montreal Edmonton, Winnipeg and Calgary.

Deutsche Maschinenfabrik, A. G., of Duisburg, Germany, have issued one of the most completely illustrated catalogs that has reached *The Canadian Engineer* office for some time. Its title, "Who We Are and What We Do," indicates the contents. Photographs are shown of the founders and present managers, together with a great many views of the works and offices. In addition, there are over seventy large pages replete with excellent illustrations of installations of the many different kinds of machinery manufactured by this firm. Among their lines are mining machinery, blast furnace plants, steel works and rolling mills, cranes and transporting appliances, ship berths, harbor and wharf-cranes, and structural steel work. The catalog is in English, and is very attractively arranged. It is being distributed by Gerald Lomer, Limited, Fraser Building, Montreal, who are the Canadian agents.

COAST TO COAST.

Dawson, Y.T.—Dawson has still in consideration plans to secure a water service.

Toronto, Ont.—The net profits of the Toronto Hydro-Electric Commission are approximately $150,000 for the past year. Last year's statement showed a profit of $13,000.

Toronto, Ont.—Freight service has been promised by January 1st over the C.P.R.'s short line between Toronto and Montreal—e.g., the Campbellford, Lake Ontario and Western Railway.

Toronto, Ont.—Chairman P. W. Ellis of the civic Hydro-Electric Power Commission, has reported for the first nine months of 1913, an increase over the corresponding period of 1912, in sales, 100 per cent.; and in purchase, only 40 per cent.

South Vancouver, B.C.—The proposal that the municipality should construct and control an electric plant is coming more and more into favor among the citizens, though there is still much divergence of opinion upon the question as to whether such a plant can be run economically or not.

Ottawa Ont.—It is understood that President Wilson of the United States has communicated with the Canadian Government suggesting a conference of representatives from the two governments to consider the question of mutual action and possible means of improving boundary waters either for navigation or for power business.

Vancouver, B.C.—A suburban train service will be inaugurated on the line of the Pacific Great Eastern from North Vancouver to Dundarave by December 31 of this year, according to Mr. D'Arcy Tate, vice-president of the road. Already grading is practically finished between North Vancouver and Dundarave, and steel is now being laid.

Calgary, Alta.—The greatest reform in the railway dispatch system of the world has been practically completed. All the C.P.R. trains in Alberta will now be dispatched by telephone instead of telegraph, with the exception of that district from Crow's Nest to Kootenay Landing. Men from Montreal are putting in the apparatus at each of the stations.

Ottawa, Ont.—The public works department at Ottawa has prepared estimates totalling $50,000,000, an amount exceeding that of last year by about $2,000,000. This outlay is not necessitated by a large program of new works, but rather those already in progress, by extensive constructions proceeding principally in harbor improvements, dredging, and the construction of drydocks.

Victoria, B.C.—The results of the analysis of water in Elk Lake, made by City Analyst Birch, in view of the possibility of its use as a future water supply, are not encouraging. Mr. Birch states that, roughly speaking, there is four times as much organic matter in Elk Lake as in samples taken from the Goldstream supply. Further experiments are to be made by the analyst.

Vancouver, B.C.—Motors for the automatic gates which have been placed by the C.P.R. to protect its level crossings at the North Vancouver Ferry slip and other docks near the foot of Columbia Avenue, are being installed and the barriers will be ready for service in a few days. The gates will slide up and down on the lift principle. They can be governed individually or collectively.

Vancouver, B.C.—The temporary dam across False Creek near the Main Street bridge built in connection with the reclamation operations, has been completed. The barrier is built of rip-rap filled with loose rock and is intended to keep the material deposited by dredging for the channel west of the bridge from drifting back with the tide. It will be replaced later with a permanent retaining wall.

Vancouver, B.C.—Word has been received in Vancouver of a rock slide which occurred at Sea Bend Bluff, near Ruby Creek, completely covering the double tracks of the C.P.R. with rock debris. Rocks, some of which weigh as much as 100 tons, have buried the track 60 feet deep for a distance of 300 feet. Dynamite is being used to remove the blockade, and a temporary track has been built around the slide.

St. Catharines, Ont.—Track laying on the extensions of the Niagara, St. Catharines and Toronto railway from this city to Niagara-on-the-Lake has been completed, and a temporary passenger service will be opened in two weeks. A spur freight line to Port Weller, the lower entrance to the new Welland Ship Canal, is now open, and material and machinery are being hauled for work on the land excavation on No. 1 section.

Winnipeg, Man.—City officials have inspected the new reservoir on Logan Avenue and McPhillips Street, and report the construction in satisfactory condition, and ready for the pumping in of water. The total cost of the new reservoir, which will hold about 18,000,000 gallons of water, will be about $300,000, and with the other city reservoirs it will provide a storage of about 24,000,000 gallons of water, or enough to supply the whole city with water for three days in case of need.

Thorold, Ont.—The Confederation Construction Company, contractors for the Government, in the undertaking of

the diversion of the G.T.R. main line, so that it may erect a bridge at a suitable point, are making rapid progress with the work involved. Steam shovels, locomotives and dump cars are busy at the deep cut being made on the eastern side of the town, where houses have had to be removed or demolished. And on the cut south of the town, good progress is also reported.

Rossport, Ont.—The engineers in charge of the now famous sink-hole at Rossport which has been tying up transcontinental traffic from time to time since September, claim that it will be impossible for the ballast to sink further. Many thousand tons of ballast have been necessary to fill up the sink-hole sufficiently to allow of the passage of trains. In the opinion of many, a steel trestle arch will ultimately have to be erected at Rossport to eliminate permanently the possibility of further difficulty or disaster.

Guelph, Ont.—The annual report of the Guelph Street Railway is one of the best in its history, recording increase of traffic throughout the system, and especially since the opening to service of St. Patrick's Ward extension. The total receipts were $40,816.09; total expenditures, $33,771.33; and resulting profits $16,045.66. After an estimate for appreciation was deducted from this amount, the net profit was fixed at $6,391.55. The report recommends that ratepayers be asked for $17,000 to improve the service.

Nelson, B.C.—Constructed entirely by Doukhobor labor, under supervision of a Vancouver firm of consulting engineers, the new steel and concrete suspension bridge over Kootenay River at Brilliant, near Nelson, has been completed at a cost of $45,000. The Government contributed $20,000 of this amount, as the bridge, which saves the Doukhobor community, is on the highway route between Nelson and Trail. The main span is 331 feet in length. Four concrete pillars 48 feet in height support the span and cables.

Toronto, Ont.—The dispute between the Etobicoke Township Council and the Toronto Suburban Railway Company in reference to the protection of crossings, has been practically settled by the Railway Board; and, as a result, work has recommenced on the Toronto to Guelph radial extension, and has advanced to the district west of Islington. The original plans have been greatly improved through the efforts of the railway commissioners, though the council was not entirely successful in its appeal for subways at certain points.

Moose Jaw, Sask.—It is reported that the high pressure mains being laid in Moose Jaw, have been completed, with the exception of a connection at one street intersection; but the system can be operated without this. The levelling of the tops of the trenches is now proceeding, and a final test of the system will be made very soon, when the pressure in the pipes will be raised to the 300-lb. mark. The fire brigade is to be supplied with hose for high pressure purposes when new motor apparatus has been ordered; so that the new system may be available in case of fires.

Niagara Falls, Ont.—The simultaneous peak load of the Hydro-Electric system recently exceeded the 50,000 h.p. mark of consumption, purchased by the commission from the Ontario Power Development Company at Niagara Falls. The breakers automatically cut the circuit and an interruption of five minutes affected the entire hydro-electric zone. As a consequence of the expansion of business, the peaks of the various municipalities overlapped at their maximum. Another interruption has been forestalled, however, by a higher adjustment of the breakers.

London, Ont.—It has been stated by the Hon. Adam Beck that before the end of 1913, hydro-electric distribution lines will be serving the farmers from end to end of the county. The line from London to Dorchester, and thence to Thamesford, is well nigh completed; and three lines—one, from London to Lucan, and thence to Ailsa Craig; another, from London to Port Stanley, using the London and Port Stanley Railway as a distribution main line; and the third, from London to Lambeth, Delaware, Mount Brydes, Strathroy, and Glencoe—are projected.

Estevan, Sask.—Engineer Miller, who is in charge of the C.N.R. grade construction out of Estevan, will have the road bed ready for the laying of track by December 1st. Culverts and grading from Bienfait to Estevan have been completed, and steel has arrived at Bienfait, further consignments being on the way. It is not expected that the work of laying track will exceed two weeks. In connection with the question of the construction of a transfer line by the C.N.R. at Estevan to link its two roads, which is being opposed by the C.P.R., Mr. Spencer, traffic expert of the board of railway commissioners, who was authorized by the board to examine local conditions, has visited Estevan, and has made a thorough investigation. It is quite expected that his report to the commission will result in the immediate order for the construction of the transfer track.

PERSONAL.

H. C. ANDREWS, of Chambers, Limited, Toronto, sailed for England last week on a six weeks' trip.

J. W. PORTER, who succeeded J. B. Armstrong as chief engineer of the Hudson Bay Railway, has assumed his new duties in Winnipeg.

R. O. WYNNE-ROBERTS, consulting engineer, Regina, Sask., has been on a trip through eastern Canada, visiting Ottawa, Montreal, Toronto and London.

A. H. HARKNESS, B.A.Sc., consulting engineer, Toronto, addressed a large meeting of the members of the University of Toronto Engineering Society on Wednesday, Nov. 26th, on the Construction of Modern Skeleton Frame Buildings. The lecture was well illustrated by lantern slides.

F. A. CREIGHTON, M. Can. Soc, C.E., who has been with the city of Prince Albert as manager of the Hydro-Electric Development at La Colle Falls, has opened an office in Winnipeg, where he will engage in the practice of civil engineering as consulting and supervising engineer. Mr. Creighton has had some twenty-two years' experience in engineering work, and has been with the city of Prince Albert since he was appointed city engineer in 1907.

OBITUARY.

The death is announced in Winnipeg of Mr. Geo. McPhillips, a well-known pioneer surveyor and engineer. Mr. McPhillips was a native of Richmond Hill, Ont., and was for many years chief surveyor for the Canadian Pacific Railway, western division. Death, on November 20th, terminated a long illness.

The death occurred at Montreal recently of Mr. A. C. Brady, assistant superintendent of C.P.R. terminals. Mr. Brady, who had been associated with the C.P.R. for 24 years, was a son of Mr. Frank Brady, general manager of the Intercolonial Railway.

On November 17th, Mr. Russell D. Willson, assistant city engineer of Winnipeg, met instant death from contact with an electric current of 13,200 volts. While on a tour of inspection of the well houses of the city waterworks system, Mr. Willson, in company with one of the engineers

of the city waterworks department, was making a careful examination of the machinery in one of the units about ten miles north of the city. While testing a lightning arrestor switch, Mr. Willson came simultaneously in contact with an iron railing, thereby causing instant death.

Mr. Willson is a graduate in engineering of the University of Toronto. His first engineering work, carried on during his university course, was in connection with the original surveys of the Toronto-to-Sudbury line of the Canadian Pacific Railway, with Mr. Hugh D. Lumsden in charge. In 1899, he joined the engineering staff of the C.P.R. in Toronto, and became associated later with the Sturgeon Falls Pulp and Paper Company. In December, 1900, he returned to Toronto, resuming his academic course in civil engineering and graduating in the following spring. In May, 1901, he accepted an offer to go to Winnipeg with the Canadian Northern Railway, and spent four years on its engineering staff, leaving to enter the employ of the city, where he was given charge of outside work for the city waterworks department. In February, 1908, Mr. Willson became assistant city engineer, which position he held up to the time of his death, with practically complete charge of the construction and operation of the waterworks department.

Russell D. Willson.

The late Mr. Willson was 34 years of age, and was born at Sharon, Ont. He was a member of the Canadian Society of Civil Engineers and was regarded by the profession generally and all others in touch with his work as one of the foremost civil engineers especially in municipal work in Western Canada.

The death is announced at Montreal of Mr. P. A. Peterson, for many years and until 10 years ago, chief engineer for the Canadian Pacific Railway, and retained by the same road as consulting engineer, after his retirement from active duties.

Mr. Peterson was born at Niagara Falls, 74 years ago. He is a graduate of the University of Toronto. He was associated with the construction of both the Intercolonial Railway, and the Canadian Pacific Railway. He was a member of the American Society of Civil Engineers and of the Institution of Civil Engineers of Great Britain; and was president of the Canadian Society of Civil Engineers in 1894.

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Annual Meeting, December 2-5, 1913.

Attention is called to the diversified program of the annual meeting of the American Society of Mechanical Engineers, to be held in the Engineering Societies Building, 29 West Thirty-Ninth Street, New York.

Papers will be presented on the following subjects:—

Boilers and their operation. Cement. Enameling. Fire protection, with special reference to turbo-generators, oils, and the novel use of sprinkler systems. Gas measurement. Gas power engineering. Lineshaft bearings. Machine tools. Management. Properties of steam. Rope drive. Steel railway cars. Textiles, covering mill engineering. Vacuum cleaning.

The professional sessions will be held in the mornings, while the afternoons will be devoted to simultaneous sessions in which special subjects, according to the above list, will be taken up. Excursions will be held at various times during the meeting. Dr. W. F. M. Goss, the president of the society, will deliver his presidential address on Tuesday evening, December 2nd.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

A meeting of the Electrical Section of the Canadian Society of Civil Engineers was held in Montreal on November 20th. Mr. H. B. Dwight, A.M.Can. Soc., C.E., read a paper entitled "The Use of Synchronous Condensers with Transmission Lines." The Mechanical Section of the society will meet on December 4th.

The Vancouver Branch held a meeting on November 25th, at which Mr. R. F. Hayward, M.Am. Soc., C.E., described the Hydro-Electric development at Stave Falls.

The annual convention and dinner of the B.C. members of the society will be held in Vancouver on December 12-13th.

COMING MEETINGS.

AMERICAN INSTITUTE OF ARCHITECTS.—Forty-seventh Annual Convention, to be held in New Orleans, La., December 2nd, 3rd and 4th. Secretary, Glenn Brown.

AMERICAN SOCIETY OF REFRIGERATING ENGINEERS.—Annual Meeting will be held in New York, December 2nd to 5th. Secretary, W. H. Reed, 154 Nassau Street, New York City.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—The Annual Meeting will be held in New York, December 2nd to 5th, 1913.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS.—Annual Meeting to be held in New York, December 10th to 13th. Secretary, C. D. Odsen, Polytechnic Institute, Brooklyn, N.Y.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS.—Seventh Annual Convention will be held at Great Northern Hotel, Chicago, December 29th to 31st. Secretary, I. W. Dickerson, Urbana, Ill.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

Barrett Specification Roofs

If you should specify merely "a five ply tar-and-gravel roof" instead of a "Barrett Specification Roof"—

You *might* get as good a roof as a Barrett Specification Roof though built somewhat differently—

But on the other hand, you may get materials of uncertain qualities,—

Or a roof with little or no pitch between the layers,—

Or a scanty surface coating of pitch and gravel—

And you wouldn't know about it until a few years later—*when the roof leaked*—

But if you put the Barrett Specification into your building specifications and see that it is carried out, you are sure—

1. That the materials will be right,
2. That they will be used in the right amount and in the right way,
3. That your roof will last upwards of twenty years without another cent of expenditure,
4. And that the cost per foot per year of service will be lower than it could possibly be with any other kind of roofing.

As Barrett Specification Roofs cost less than any other permanent roof to begin with and as their maintenance cost is nothing, the unit cost comes down to about ¼c. per square foot per year, a figure unapproached by any other roof covering.

Copy of the Barrett Specification with tracing ready for incorporation into your building plans, sent free on request. Address nearest office.

Special Note We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding. If any abbreviated form is desired however the following is suggested: ROOFING—Shall be a Barrett Specification Roof laid as directed in printed specification, revised August 15, 1911, using the materials specified, and subject to the inspection requirement.

ORDERS OF THE RAILWAY COMMISSIONERS
OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20814—November 13—Approving plan and specifications of drain known as "Ellice Maitland Relief Drain," to be constructed under C.P.R. on Lots 29 and 30, Con. 18, Tp. Elma, Ont.

20815—November 12—Authorizing C.N.R. to operate trains over Thirteenth Street, Brandon, Man., without first being brought to a stop; cars of Brandon Mun. St. Ry. Co. be brought to a stop before proceeding over crossing and conductors of such cars operate levers of the interlocker.

20816—November 12—Directing that C.P.R. and G.N.W. Tel. Cos. remove their wires from poles on Queen St. North, between King and Weber Sts., Berlin, Ont. Applicant (City of Berlin) make provision by which said Cos. have right to string wires on Frederick and King Sts. to enable them to reach their offices, on King St.; poles be removed from Queen St. N.

20817—November 11—Directing C.L.O. and W. Ry. (C.P.R.) to construct an undercrossing on farm of A. R. Farewell, Town of Oshawa, Ont., at a point on old farm road where fill is 15 ft., near east end of lot, and about 300 ft. east of level crossing. Work be completed within three months from date of this order.

20818—November 14—Authorizing C.P.R. to construct, subject to conditions contained in By-law No. 1747, excepting clause 8 of such By-law, spur for Peter Hamilton Co., Limited, across Sherbrooke St. and along Water St., Peterboro, Ont.

20919—November 14—Authorizing G.T. Ry. to construct siding to premises of Grand Gypsum, Limited, Tp. North Cayuga, at Nelles Corners.

20820—November 14—Authorizing G.T.R. to construct, subject to conditions of consent, siding into premises of Dominion Tar and Ammonia Co., Limited, part Lot 16, Con. 2, Tp. Barton, now City of Hamilton, Ont.

20821—November 13—Authorizing C.N.R. to construct across Winnipeg Electric St. Ry. Co. on Jubilee Ave., Winnipeg, Man., subject to and upon certain conditions.

20822—November 15—Authorizing C.P.R. to operate Bridge No. 45.6 on Orford Sub. Div., Eastern Division, Province of Quebec.

20823—November 17—Authorizing G.T.P. Ry., subject o conditions contained in Order-in-Council, to construct bridge across Nechaco River, at mileage 371.4, Prince Rupert Easterly, B.C.

20824—November 15—Authorizing G.T.R. to operate three (3) bridges, No. 217, mileage 13.07 over Jacques River, Que.; 2, No. 232, mileage 36.85, over English River, Que., and 3, No. 236, mileage 43.82, over Chateauguay River, Que.

20825—November 17—Approving location Montreal and Southern Cos. Ry. from Central Vermont Ry. Station, at St. Cesaire, through Parish of St. Cesaire, Co. Rouville, Que., to boundary line between Parish of St. Cesaire and St. Paul de Abbotsford.

20826—November 14—Amending Order No. 20514, dated Oct. 6th, 1913, by substituting words "known as Con. 9, between Counties of Haldimand and Norfolk, on which Townsend Station is located," for words, "at Townsend Station between Cons. 8 and 9, in Co. of Haldimand," in recital of said Order.

20827—November 14—Authorizing C.P.R. to construct bridge No. 92.7 on Toronto Subdivision, Ont. Div. Don Viaduct, near Donlands, Co. York, Ont., subject to certain conditions.

20828 November 14—Authorizing C.P.R. to take, for purpose of a double track, certain parcel of land in Tp. York, Co York, Ont.

20829—November 17—Amending Order No. 18837, dated March 12th, 1913, by substituting "plan 'B,' dated Feb. 15th, 1913, and revised Oct, 30th, 1913," for "plan 'A,' dated Feb. 15th, 1913," approved under said Order; and that plan of permanent structure, dated Oct. 15th, 1913, as revised Nov. 5th, 1913, be approved.

20830—November 18—Approving revised location C.N.R. Calgary-Southerly Line through Tp. 22, R. 29, W. 4 M. mileage 10.59 to 13.21; through Tps. 22 and 21, R. 29, W. 4 M. mileage 13.74 to 16.16; through Tp. 18, R. 29, W. 4 M. mileage 35.49 to 38.05; and through Tps. 10 and 9, Rgs. 25 and 26, W. 4 M. mileage 93.21 to 100.79.

20831—November 18—Amending Order No. 20609, dated Oct. 15th, 1913, by striking out clause (b) of paragraph 1, in operative part of said Order.

General Order No. 114—November 12—Approving general form of contract to be entered into between Bell Telephone Co. of Canada and any other company, municipality, or corporation having authority to construct and operate a telephone system or line, for interchange of telephone messages or service passing to or from their respective telephone systems and lines, the division or apportionment of telephone tolls, and management, working, or operation of their respective telephone systems or lines.

20832—November 15—Granting leave to City of Edmonton, Alta., to cross, at level, with its municipally-owned electric street railway, with necessary poles and wires to transmit power, the line of C.N.R. where same intersects Athabasca Ave., said city, subject to certain conditions.

20833—November 18—Authorizing G.T.R. to construct additional track across John St., Village of Weston, Co. York, Ontario.

20834—November 18—Authorizing Mun. Corporation of Town of Sudbury, Ont., at its own expense, to construct highway crossing over Stobie Branch of C.P.R., to connect Bond St. with Notre Dame St., Sudbury, Ont.

20835—November 18—Authorizing Montreal and Southern Cos. Ry. to construct bridge to carry its line across Yamaska River, near St. Cesaire, Quebec, subject to terms of consent of Parish of St. Cesaire.

20836—November 18—Approving location C.P.R. station at Gravel, mileage 32.50, Lake Superior Div. Nepigon Sub. Div., Ontario.

20837—November 18—Authorizing St. Lawrence and Adirondack Ry. Co. to construct highway across its railway, just south of Bellevue Station, Que.; cost of construction be borne by Parish of Chateauguay, Que.; cost of maintenance be borne by Railway Company.

20838—November 19—Approving plans showing location and details of C.N.R. special station proposed to be constructed at Gravelbourg, Saskatchewan.

20839—November 19—Amending Order No. 8627, dated Oct. 21st, 1909, by adding after word "follows," in second line of paragraph 7 of Order and before words "the sum," words following, namely, "twenty per cent. of the cost of the said works, not to exceed."

20840—November 18—Authorizing C.P.R. to construct spur for Joseph Elie, Montreal, Que.

20841—November 18—Authorizing G.T.P. Branch Lines Co. and C.P.R. Co. to operate their trains over crossing at Frobisher, Sask., without their first being brought to a stop.

20842—November 19—Authorizing C.P.R. to operate trains over drawbridge over Kaministiquia River, at Fort William, Ont., without their first being brought to a stop.

20843—November 19—Authorizing C.P.R. to construct spur for Quaker Oats Co., Saskatoon, Sask.

MANNESMANN TUBES

Six Hundred Authorities Are Using Mannesmann Tubes

in Great Britain in varying quantities up to 15 miles; in Canada, to 17 miles.

Seven hundred miles of weldless steel spigot and faucet tubes —quite apart from flanged tubes and lapwelded spigot and faucet tubes—are in use in the United Kingdom, as well as large quantities in Canada, Australia, South Africa, South America, India, China, New Zealand and Europe.

We are constantly adding new customers to our list, and, what is of even greater significance, more frequently still receiving repeat orders.

Solid drawn tubes are used in places where it is impossible to use cast-iron pipes or lapwelded tubes, as well as in places where the conditions are more normal.

In the past five years the sale of Mannesmann weldless steel spigot and faucet tubes (home trade alone) increased one thousand per cent., and during the last financial year reached the figure of about 5,000 tons, equal to 15,000 tons of cast-iron, in addition to a large export business.

MANNESMANN TUBE CO. LIMITED
51 Victoria Square, MONTREAL

BOOKLETS ON REQUEST

20844—November 11—Directing that C.N.R. and G.T.P. Ry. Cos. construct transfer track near Dana, Sask., subject to certain conditions.

20845—November 17—Directing that C.L.O. and W. Ry. (C.P.R.) install an improved type of automatic electric bell at crossing of highway between Cons. 3 and 4, Tp. Tyendinaga, Co. Hastings, Ont., at mileage 61.87, bell to be installed by time line is opened for traffic.

20846—November 19—Establishing collection and delivery limits of Express Companies in City of Hamilton, Ontario.

20847—November 19—Authorizing C.P.R. to open for traffic following portions of double track on Lake Superior Div. Ont., Azilda, mileage 86.0 to 95.5, mileage 113.2 to Cartier, mileage 114.6, Cartier Subdivision. Nemegos, mileage 120.9 to 125.0, Poulin, mileage 127.0 to 130.0. Chapleau Subdivision, Esher, mileage 7.1 to 9.0, mileage 18.9 to Goldie, mileage 34, on White River Subdivision. Redlite, mileage 11.2 to 21.0, Schreiber Subdivision, and Selim, mileage 9.3 to Rossport, mileage 14.3, mileage 29.0 to Gurney, mileage 39.1, Nipigon Subdivision.

20848—November 18—Authorizing G.T.P. Ry. to reconstruct bridge across Kitssumkaylum River, at mileage 91, Prince Rupert East, British Columbia.

20849—November 12—Directing that C.N.R. provide suitable crossing over its tracks where same cross Fort Garry Boulevard, Rural Mun. of Fort Garry, Man.; cost of constructing and maintaining said crossing be borne by Municipality.

20850—November 19—Authorizing Canada Southern Ry. Co. to construct branch line from a point on its railway east of Welland Station, Tp. Crowland, Co. Welland, Ont., to a point in Lot No. 22, Con. 5, Tp. Humberstone, Co. Welland, crossing Ontario Road, Commercial St., Dover St., Dain St., and Town Line Road between Tps. Crowland and Humberstone.

20851—November 19—Relieving C.P.R. from providing further protection at crossing of highway, being first crossing east of station building at Tyndall, Man.

20852—November 17—Authorizing N. St. C. & T. Ry. to open for traffic its line between city of St. Catharines and town line between Tps. Grantham and Niagara, Ont., distance of 7.1 miles, for a period of three months from date of this Order. 2. Authorizing Ry. Co. to operate cars over crossing of G.T.R. at Welland Ave., St. Catharines; and pending installation of interlocking plant, all trains and cars be flagged over crossing by a day and a night watchman.

20853—November 20—Directing that, within 3 weeks from date of this Order, C.N.R. extend siding at Sleeman, Ont., so as to accommodate thirty-eight (38) cars.

20854—November 13—Authorizing City of Edmonton, Alta., to operate its cars over G.T.P. Ry. on Twenty-first St., Edmonton, pending installation of half-interlocker; cars to come to a stop and be flagged over crossing by conductors of Applicant's Street Railway.

20855—November 20—Authorizing C.P.R. to construct siding for Cowan Co., Limited, Toronto, Ont., at Parkdale, Ont.

20856—November 20—Directing Edmonton, Dunvegan and B.C. Ry. to construct farm crossing, to road allowance, on farm of Wm. Dives, Independence, Alta., on N.E. ¼ Sec. 36-57-27, W. 4 M., Alta.; work to be completed within 20 days after approval of plan.

20857—November 19—Directing G.T.P. Ry. forthwith to construct No. 1 B.R.C. station and platform at Telkwa, B.C.; to be located on south side of track at point just west of cut, near east end of curve; construct also, at same time, siding to hold at least 12 freight cars, at west side of bridge, at or near point shown in red on plan; and provide wayfreight and local passenger service at Telkwa.

20858—November 20—Authorizing Town of Stony Plain, Alta., at its own expense, to construct Main St. across C.N.R., Town of Stony Plain, Alta.

20859—November 21—Directing Whyte St., Edmonton, Alta., be protected by gates installed by C.P.R., and operated by day and night watchmen. 20 per cent. of installing gates be paid out of Ry.-Grade Crossing Fund, 2/3 remainder by Ry. Co., and 1/3 by City; wages of watchmen—2/3 by Ry. Co., and 1/3 by City.

20860—November 21—Establishing collection and delivery limits of Express Cos. in Town of Cochrane, Ont.

20861—November 20—Dismissing complaint Otis-Fensom Elev. Co. against proposed 6th-class rating in Supplement No. 2 to Can. Freight Classification No. 16, submitted by Can. Freight Association for approval of the Board.

20862—November 21—Directing that C.N.R. trains be brought to a stop before proceeding over Fournier and Browning Avenues, and operated over such crossings at a speed not exceeding four miles an hour; posts showing word "Stop" to be erected at east side of Fournier Avenue and at west side of Browning Avenue, at points 75 feet from crossing. 2. Ry. Co. make an entrance for vehicular traffic from driveway or lane at back of station building, situated midway between Fournier and Browning Avenues: Applicant (council town of Carman, Man.) undertaking to trim trees at south-west corner of Browning Avenue, to a height of 22 feet above the rail.

20863—November 20—Authorizing C.P.R. to operate its trains over the bridge across McKellar River, Fort William, Ont.

20864—November 19—Authorizing C.P.R. to construct spur for J. L. Abbott, Toronto, Ont., from a point on northerly limit of right of way, in W. ½, Lot 16, Con. 7, Tp. Eldon, Co. Victoria, Ont., at mileage 35.07, Ont. Division, Port McNicoll, Subdivision at Balsam Lake.

20865—November 21—Establishing collection and delivery limits of Express Companies in town of Sudbury, Ont.

20866—November 21—Establishing collection and delivery limits of Express Companies in town of North Bay, Ont.

20867—November 20—Authorizing city of Winnipeg, Man., to extend Godfrey Avenue, across Oak Point Branch of C.N.R., Winnipeg.

20868—November 20—Directing that C.P.R. construct bridge with a roadway 30 feet wide over its tracks on Eighth Avenue West, in city of Moose Jaw, Sask., and an extension sidewalk 6 feet wide on one side of said bridge. Cost of construction be apportioned:—$5,000 out of Ry. Grade-Crossing Fund, 75 per cent. of remainder by Ry. Co. and 25 per cent. by city of Moose Jaw. Substructure be maintained by Ry. Co. roadway and sidewalk by city. Order No. 17206, dated July 25, 1912, be rescinded.

20869—November 21—Amending Order No. 16978, dated July 11th, 1912, to provide that C.L.O. and W. Ry. (C.P.R.) construct under Oshawa Electric Ry. Co., on Simcoe Street, town of Oshawa, Ont., as shown on plan "A," dated November 5th, 1913, instead of as shown on plan approved under said Order.

20870—November 13—Approving location G.T.P. Branch Lines Co.'s Mountain Park Coal Branch from S.E. ¼, Sec. 33-45-23, to N.E. ¼, Sec. 32-48-21, W. 5 M., mileage 0 to 30.24, District North Alta., Alta.

20871—November 21—Authorizing G.T.R. to construct siding for Arthur Sherk, Whitehall, Ont., into premises of Northern Veneer Co., Limited, on Lot 28, Con. 11, Tp. McMurrich.

20872—November 21—Authorizing G.T.R. to construct siding into premises Messrs. Whiteside and Arnold, on Lots 2 and 3, south of Tiffin Street, Allandale, town of Barrie, Ont.

20873—November 11—Authorizing Rural Mun. Keyes, No. 303, Sask., at its own expense, to construct highway crossing over C.N.R. between Secs. 25 and 36, Tp. 33, Rge. 1, W. 2 M., Saskatchewan.

20874—November 20—Directing that First Street and Namayo, Syndicate and Alberta Avenues, Edmonton, Alta., be protected by gates installed by Canadian Northern and G.T.P. Rys., and operated by day and night watchmen; 20 per cent. of cost of installing gates at said crossings of First Street and Namayo and Syndicate Avenues respectively, be paid out of Ry. Grade Crossing Fund: remainder be paid in equal proportions by Ry. Cos.; city to pay wages of watchmen at said crossings; cost of maintenance of gates be divided equally between Ry. Cos.; 20 per cent. cost of installing gates at Alberta Avenue be paid out Ry. Grade Crossing Fund, remaining 80 per cent.:—two-thirds by Ry. Cos. and one-third by city. Cost of maintenance of gates and wages of watchmen be paid two-thirds by Ry. Cos. and one-third by city.

HOFFMANN
Journal Bearings

have curved ball races, accurately ground and polished, in two hardened concentric rings of finest steel. The single row of balls run in an anti-friction cage of drawn gunmetal—or the bearings are filled with balls, without a cage, when required. The rings are ground absolutely true, so that the bearings can be readily and accurately aligned.

HOFFMANN
Thrust Bearings

are undoubtedly the finest Ball Thrust Bearings ever put on the market. They are made single and double, to suit any requirements, and have been adopted as standard by the leading engineering and manufacturing firms the world over.

HOFFMANN
Steel Balls

are the foundation of the superiority of Hoffmann Bearings. They are of the finest High Carbon Chrome Steel, with surfaces glass-hard and interiors somewhat softer. Each ball is guaranteed to be a perfect sphere, correct to standard size within one ten-thousandth of an inch.

Put your bearing problems up to us. Hoffmann Ball Bearings have successfully carried loads up to 500,000 lbs., at speeds up to 30,000 revolutions per minute.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

—Denotes an item regarding work advertised in *The Canadian Engineer*.
+—Denotes contract awarded. The names of successful contractors are set in CAPITALS.

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of *The Canadian Engineer* referred to.

RAILWAYS—STEAM AND ELECTRIC.

+—Calgary, Alta.—The contract has been awarded the CARTER-HALLS-ALDINGER COMPANY of Calgary, for the construction of a temporary station, freight shed, and office building for the C.N.R. company. The building will cost approximately $100,000, and will be completed by the end of December.

Fredericton, N.B.—C.P.R. engineers and bridge experts have made an examination of the Southampton railway line, and Mr. James K. Pinder, M.L.A., has announced that it will be taken over within a few days for operation as a part of the C.P.R. system.

Hamilton, Ont.—The Ontario Railway Board has decided that the incline railway company must put its line in safe condition and resume operations. No date was set for the completion of repairs, this being left open pending a report from the engineer of the board.

London, Ont.—The G.T.R. will not build the Port Burwell-London line, according to the statement made in London by Superintendent Wittenberger. The Pere Marquette will continue to haul coal for the company.

+—Moncton, N.B.—Orders have recently been given by the I.C.R. to the LOCOMOTIVE WORKS at Montreal, Kingston, and Toronto, respectively, for 15, 9, and 5 locomotives, of which 5 are switch engines, and the rest heavy freight—4 of the Pacific type, and 20 consolidated.

Montreal, Que.—The Canadian Autobus Company has submitted its offer to the city, in which it shows that it is ready to build 7 or 8 miles of subway to serve the heaviest lines of traffic in Montreal, at an estimated cost of $20,000,000. Certain conditions are to be agreed upon; among others, the company requests a franchise for thirty years with the option of the city acquiring the plant and equipment at the end of that term at its actual value plus 10 per cent. The work is to be started in 1914 and finished in 1918.

Montreal, Que.—Two organizations are offering to supply the additional transportation facilities urgent in Montreal. The Montreal Tramways Company has applied for an extension of its charter, promising underground railways. The Canadian Autobus Company has intimated to the city that it is prepared to construct tubes serving both the down-town and uptown districts

Montreal, Que.—A committee has been appointed by the council of the board of trade to consider the revised contract between the city of Montreal and the Montreal Tramways Company, and to report to council.

Ottawa, Ont.—Application to Parliament will be made to incorporate the All Red Line Railway, which proposed to build from Cape St. Charles, Labrador, to Lake Mustassi, crossing the Wottaway River to the boundary between Quebec and Ontario, and so on in a north-westerly direction to a crossing of the Hudson Bay Railway at Cormorant Lake, and thence to the Peace River country, and on to a terminal in British Columbia at Dean's Inlet on the Pacific Ocean. Branch lines are proposed to connect the railway with the cities of Quebec and Winnipeg, and with the Yukon by way of the Peace River Valley. The application is made by J. K Dowsley, of Prescott, solicitor for the promoters.

Ottawa, Ont.—Application is being made to parliament for the incorporation of the Ungava Railway Company, which proposes to build a railway from Aylmer Sound, on the St. Lawrence, to the Hudson Bay post at Whale River.

Port Arthur, Ont.—Sir Donald Mann has purchased the 14 miles of North-Eastern Railway, built two years or more ago to serve several miles in the inland region from the head of the Portland Canal. It is a strategic piece of railway, commanding the Pacific terminus of the shortest transcontinental route in Canada.

St. Thomas, Ont.—Mr. Geo. B. Woods, of Toronto, and Mr. W. N. Warburton, of London, Vice-President and General Manager, respectively, of the London and Lake Erie Transportation Company, operating between London and Port Stanley, state that the company is considering extensions of its line; one for St. Thomas to Aylmer and Port Burwell at a cost of over $300,000, including a branch line to Sparta; and one from London to Ingersoll, Woodstock and Brantford. Another extension from Lambeth to Delamere is planned for the near future.

Toronto, Ont.—A by-law will be submitted to ratepayers, Jan. 1st, to authorize the purchase of the Sunnyside-to-the-Humber section of the Toronto and York Radial Railway Company's Mimico line for the sum of $81,615.13.

Toronto, Ont.—Auditor John MacKay has reported to Mayor Hocken that the purchase of the Toronto Street Railway and Toronto Electric Light properties will justify itself financially. The purchase of the railway company, its consolidation with the civic car lines and extension into an ideal system is compared by Mr. MacKay with the non-purchase of the company until the expiry of the franchise in 1921, and the extension of the civic car lines into the best possible system. His opinion is that the former alternative will result in a saving of three million dollars.

Toronto, Ont.—The T. & N.O. Railway has under construction steel equipment for two passenger trains, which will be ready for service early in the spring. It is the intention of this company to eliminate gradually from its service the wooden car; and to have its entire equipment of steel underframe and steel superstructure cars. It possesses already 100 steel under-frame flat cars and 100 steel underframe box cars, and claims credit as the first railroad in the Dominion to adopt the steel car.

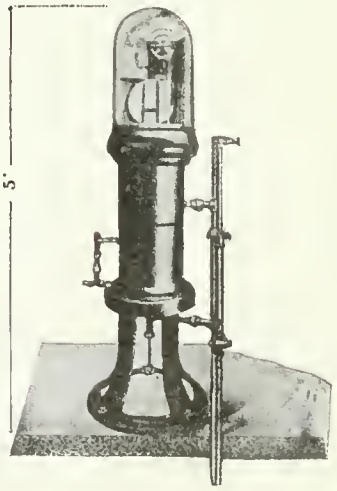
Simplex Water Meter

Type 'G' Register

adaptable and furnished with either Venturi tubes or Pitot tubes, and now fully developed and successfully tested for Triangular Notch or Rectangular Weirs.



Hot or Cold Water

Actuating power, simple shaped float in mercury.
Greatest range of flow with minimum friction through Venturi tube.
No cams—uniform graduations.
One eight-day marine clock.
Rectangular chart—daily or weekly. Total flow five dial register—glass dome or metal dome with glass doors, if desired.
Chart can be averaged with ordinary planimeter.
Indicating dial may be graduated in gallons, cubic feet, pounds or horse power.

Particulars, diagrams, tests and other data upon request

Canadian Representatives:
Messrs. FRANCIS HANKIN & CO.
MONTREAL TORONTO VANCOUVER

Vancouver, B.C.—The Coquitlam council wrote recently to the civic bridges and railways committee of Vancouver City Council asking for assistance in obtaining an extension of an interurban line from New Westminster to Coquitlam. The committee did not favor the scheme, but supported the plan for reaching Coquitlam by an extension of the Hastings street line or a line on the Johnston road.

Winnipeg, Man.—Tenders will be received up till December 4th for one steam locomotive with separate fender and snow plow. Plans and specifications may be obtained from M. Peterson, Esq., Secretary, Board of Control, Winnipeg, Man.

GARBAGE, SEWAGE AND WATER.

Dawson, Y.T.—A civic league has been formed by a large number of Dawson citizens for the purpose of co-operating with the local government for the installation of city water, light and telephone plants.

Hamilton, Ont.—Considerable damage has been effected by a break in the 20-inch water main on King William Street, when thousands of gallons of water flooded the central district of the city.

Ingersoll, Ont.—Consulting Engineer Weston, of Boston, and Engineer Thorold, of Toronto, are investigating the plans prepared by the latter for a sewerage system for Ingersoll.

London, Ont.—An engineer, acting under Consulting Engineer Willis Chipman, is daily expected in London, and it is expected that the surveys for the east end disposal plant, and for parts of the storm water system will be completed before the hard winter weather sets in.

Mimico, Ont.—The recent epidemic of scarlet fever at Mimico has been attributed to the unsanitary arrangement for the disposal of the sewage in vogue in the village. In order to guard against a repetition of the epidemic the Council are seriously considering a proposition to install a complete water and sewage disposal system. It is estimated that a complete system, including the erection of a waterworks and sewage disposal plant, together with the laying of the necessary mains, would cost nearly $340,000. Of this amount $70,000 would be raised by the issuance of debentures, while the remainder would be assessed as a local improvement covering a period of years.

Montreal, Que.—Mr. R. S. Lea, consulting engineer, has reported to the city, recommending the construction of a garbage reduction plant, to be located at some distance from the city, and the garbage to be hauled to it by rail.

Ottawa, Ont.—The acting city solicitor announced at the recent board of control meeting that the bond offered by the City Garbage Company is now quite satisfactory, and it is expected that the contract for the collection of garbage will be executed in the immediate future.

Ottawa, Ont.—The board of control has approved of the engagement of E. J. Rainboth, land surveyor, for work in connection with the Gatineau water scheme right-of-way and the land proposed to be secured around the lakes. He will get $40 to $50 a mile and $2 for the description of each parcel of land.

Ottawa, Ont.—Mayor Ellis has announced that the first contract for Gatineau water supply pipe will be let in about six weeks' time and the first contract for construction next April. It was also stated that as far as possible Canadians will be engaged upon the work.

+—Toronto, Ont.—The contract has been awarded by the board of control for the supplying and installing of an 84-inch steel conduit to be run across the island from the pure water reservoir to the south tunnel shaft, to the firm, ROGER MILLER & SONS. The contract price is $540,000; and the tender of this firm was the only one submitted.

▲—Toronto, Ont.—Tenders will be received up till January 20th for the installation of a complete mechanical filtration plant, boilers etc., at Toronto Island. Plans and specifications may be obtained from Mr. James Milne, Mechanical and Electrical Engineer, Department of Works, City Hall, Toronto. Signed, H. C. Hocken (Mayor), Chairman, Board of Control.

▲—Vancouver, B.C.—Tenders will be received up till December 1st for the construction of trunk sewers, Contract No. I. Plans and specifications may be obtained from the Burrard Peninsula Joint Sewerage Board. G. W. Phipps, Secretary.

Vancouver, B.C.—Further delay in the awarding of contract for the laying of the Point Grey partnership water main is due to lack of definite information as to the depth the pipe will have to be carried across False Creek. A statement has been requested from the Department at Ottawa, and it is hoped that the matter will be settled finally within a few days.

Vancouver, B.C.—Tenders will be received up till December 1st for the construction of trunk sewers—Contract No. I.—at the offices of the Burrard Peninsula Joint Sewerage Board, 514-518 Birks Building, Vancouver, B.C. Plans and specifications may be obtained from Geo. W. Phipps, Secretary-Treasurer, Burrard Peninsula Joint Sewerage Board.

Victoria, B.C.—Both the Sewer Loan by-law and the Waterworks by-law have been passed by the property owners of Oak Bay, B.C. $150,000 will be expended on the completion of the installation of a sewer system; and $35,000 will provide a water supply.

LIGHT, HEAT AND POWER.

Brockville, Ont.—Tenders will be received for the supplying of two 300 h.p. water-tube boilers, and for an electric-driven turbine pump. Plans and specifications may be obtained from the Brockville Water and Light Department. E. J. Philip, manager.

Claresholm, Alta.—Natural gas has been struck about six miles east of Claresholm on the property of Mr. John Sutherland, who purposes securing capital for its development.

Edmonton, Alta.—Ratepayers in Edmonton will be requested to vote on a plebiscite at the civic elections, on December 8th, upon two proposals, both designed to supply natural gas to consumers at low rates, as follows: (1) to accept the offer of the Pelican Oil and Gas Company at 15 cents a thousand feet, delivery November 1st, 1915; or (2) to expend about $300,000 for exploration work under municipal direction in the Vegreville and other gas fields.

+—Guelph, Ont.—The contract has been awarded GRINYER & COMPANY for the electrical work for Hewittson's new factory in Brantford.

+—London, Ont.—An agreement has been made between the City Gas Company and the SOUTHERN GAS COMPANY, a natural gas syndicate for the supply of gas in London, commencing April 1st. The rates in summer months will be 50 cents per 1,000 cubic feet, with 5 cents discount; and in winter, 45 cents per 1,000 up to 4,000 feet, and 35 cents when consumption exceeds this amount.

Niagara Falls, Ont.—Mr. Frederick Walker, of New York, has devised a water and power project, which will be backed by British and Canadian money, and will cost about $2,500,000. His plan is to build a suspended raceway to tap one-half of the waterfall from the Canadian Falls and one-half from the American Falls at Niagara and carry the water through the Niagara River to a point where a great power plant will be erected for the creation and distribution of electricity.

Ottawa, Ont.—The Michigan Northern Power Company and the Algoma Steel Corporation have applied conjointly for approval of a scheme to divert certain waters of the St. Mary River at the Soo to develop power for the various industries on both sides of the international boundary. The plans have been sent to the public works department at Ottawa and to the secretary for war of the United States for approval before being passed upon by the international waterways commission.

Ottawa, Ont.—A delegation from Merrickville has interviewed the Hon. Dr. Reid, acting minister of railways, and has urged that the improvements to Rideau Canal at that centre be carried out so as to provide for the development of electric power in the town.

Puslinch, Ont.—The Puslinch council has passed the motion required by the Hydro-Electric Power Commission before taking proceedings in any municipality, under the Hydro-Electric Railway Act of 1913. This was done in connection with the proposed road from Hespeler, connecting with Puslinch Lake, through Guelph to Elora, Fergus and Arthur, and from Guelph through Aberfoyle and Morriston to Puslinch Station; and also from Arthur, connecting with Mount Forest, and through the Beaver Valley to Meaford or Thornbury. This scheme, in addition to furnishing railway service, would also distribute power and light.

The Departmental House for Mechanical Goods HAS ARRIVED

What the department store is to the general public our "Mechanical Goods Departmental House" is to the engineering and contracting field.

The public takes the efficient and time-saving merchandising methods of the department store as a matter of course. In the mechanical world we offer the same convenient service.

Why lose time "shopping" around town when you can buy anything you want and of a standard quality all under "one roof"?

Our business is divided into a number of departments in order that it may be handled most expeditiously and to the best interests of our customers.

In addition to the staple articles pertaining to each department we handle a great many specialties, some of which are listed below

SCALE DEPARTMENT
- Fairbanks World-famous Scales, of all types and sizes

VALVE AND STEAM GOODS DEPARTMENT
- Fairbanks Brass and Iron Valves
- Pratt and Cady Valves
- Foster Reducing Valves
- American Steam Pressure Gauges
- Wainwright Joints
- Penberthy Oilers
- Strong Steam Traps
- Wainwright Heaters
- Burt Exhaust Heads
- American Safety Valves
- Trident Water Meters
- Palmetto Packing
- Durabla Packing
- Oster Stocks and Dies
- Tools and Fittings

ENGINE DEPARTMENT
- Fairbanks-Morse Oil Engines
- Fairbanks-Morse Marine Engines
- Fairbanks-Morse Tractors
- Farm Machinery
- Motor Boat Supplies
- Automobile Supplies

PUMP DEPARTMENT
- Fairbanks-Morse Steam Pumps
- Power Pumps
- Goulds Power Pumps
- Hand Pumps
- Combined Engines and Pumps
- Spraying Outfits
- Air Compressors
- Suburban Water Systems

ELECTRICAL DEPARTMENT
- Fairbanks-Morse Generators and Motors
- Edison Storage Batteries
- Suburban Lighting Outfits

MACHINERY DEPARTMENT
- Pratt and Whitney Tools
- Brown and Sharpe Tools
- McDougall Lathes
- Bertram Tools
- Machine shop tools of all kinds
- Wood Working Machinery

TRANSMISSION DEPARTM'T
- Fairbanks Wood Split Pulleys
- Universal Giant Shaft Hange
- Skefko Ball Bearings
- Nicholson Couplings

RAILWAY AND SUPPLY DEPARTMENT
- Fairbanks-Morse Motor Cars
- Elwell-Parker Trucks
- Barrett Jacks
- Arthur Koppel Industrial Ry. Equipment
- Fairbanks-Morse Air Compressors
- Fairbanks-Morse Hoisting Engines
- Fairbanks Trucks
- Milburn Lights
- Smith Concrete Mixers

SMALL TOOL AND SUPPLY DEPARTMENT
- Pratt and Whitney Tools
- Brown and Sharpe Tools
- Yale and Towne Hoists
- Alundum Grinding Wheels
- Crystolon Grinding Wheels
- India Oil Stone
- Parker Vices
- Union Chucks

SAFE AND TYPEWRITER DEPARTMENT.
- Dominion Safes and Vaults
- Noiseless Typewriters

TRUCK DEPARTMENT
- Mack Trucks (gasoline)

"The Departmental House for Mechanical Goods."

MONTREAL ST. JOHN QUEBEC OTTAWA TORONTO
WINNIPEG CALGARY SASKATOON VANCOUVER

+—**Regina, Sask.**—The city council has awarded to WILLANS & ROBINSON the contract for the installation of a 3,000 k.w. steam turbine and condensing plant, and a Siemen's generator, in connection with the city power plant.

Saskatoon, Sask.—The C.N.R. are endeavoring to secure a lower rate for water from Saskatoon; and in case a satisfactory agreement cannot be made, it is understood that the company will construct a separate plant.

St. Catharines, Ont.—Government engineers are surveying for the proposed big water main from Sugar Loat (west of Port Colborne) to supply lake water to St. Catharines and all other towns along the canal in the event ot the river and canal being brought to the same level. No definite decision has been announced concerning the project. The towns now taking water from the canal are requesting the Government to bear the cost of the pipe line.

Toronto, Ont.—Mayor Hocken, in his address to members of the Municipal Improvement Association on the subject of the railway deal, made the statement to the effect that at present the Toronto Hydro system is unable to lay its wires where they will give the greatest benefit, owing to the limitations on its activities imposed by the terms of the Toronto Electric Light Company's franchise of the streets. The Mayor stated further that the city will insist, in the final agreement with the vendors, that the contract to be assumed with the Electrical Development Company for the supply of Niagara power must provide a similar price for current to that now paid by the city to the Ontario Power Commission.

Toronto, Ont.—As a result of a report made by Chief Engineer Gaby the hydro commission will make a general reduction in the hydro rates of the various municipal systems.

Toronto, Ont.—At the meeting held on November 19th, the Hydro-Electric Commission authorized the closing of the contract with Owen Sound, and the ordering of the commission's engineers to immediately see about the plans and tenders for the work in hand. An expenditure of $650,000 is involved in the development of power at Eugenia Falls, and the supply of many towns en route. This line will also tie with the Collingwood connection now serving Midland, Penetang, and Barrie.

Toronto, Ont.—A reduction of 10 and 15 per cent. on the rates now obtaining in Toronto, London, and Ottawa, has been authorized by the Hydro-Electric Commission. Toronto and Ottawa were given a reduction of 10 and 15 per cent., respectively on all light and power rates; while London will have a cut off of 15 per cent. on light, and 18 per cent. on power charges.

Victoria, B.C.—An estimate has been submitted to the South Saanich municipal council by the British Columbia Electric Company for the providing of a system of street lighting for four of the wards of the municipality at a cost ot about $37,500. The council has moved that the British Columbia Electric officials be asked to consider an agreement by which the two wards omitted in the plans submitted should be included in the proposed system.

BRIDGES, ROADS AND PAVEMENTS.

Calgary, Alta.—Plans are being prepared by Mr. T. H. Mawson, city planner for Calgary, and City Engineer Craig, for a bridge across the Bow River at Center Street. They will prepare plans for a bridge at right angles, and for an oblique bridge; also for an elevated as well as a low-level bridge. It will be left to the council to choose the most aesthetic and economic scheme.

Cornwall, Ont.—The Williamsburg township council has passed a resolution in connection with the action of the Ontario Government in appointing a commission to investigate the question of better roads. The resolution urges upon the commission the necessity of improving first the market roads in each municipality, the necessity of expending assistance granted to municipalities under the direction of a government engineer, and the advisability of abolishing the present system of statute labor and of instructing the clerk to send a certified copy of this resolution to the chairman of the commission.

+—**Digby, N.S.**—The C.P.R. has given over to the FOUNDATION COMPANY of New York, the work of completing the new steel bridge across Bear River. Trouble has been caused in the course of construction by one of the piers toppling over in the mud, and Messrs. Power and Brewer have withdrawn from the work.

Edmonton, Alta.—Civic officials are investigating and considering the construction of a good thoroughfare from Forty-second Street to the Country Club's grounds. The road to the club grounds is part of the proposed river drive to Big Island.

+—**Halifax, N.S.**—The contract has been awarded by the provincial government to the STANDARD CONSTRUCTION COMPANY, of Halifax, for the building of the substructure for the Lennox Passage bridge, Richmond Co., Cape Breton. The structure will consist of nine cement piers faced with granite and will have a draw for vessels in the centre. The company will begin in the early spring and hope to complete the job by the end of 1914.

Hartland, N.B.—It is being rumored with considerable authority that a new highway bridge will be constructed, probably this winter, across the river at Hartland, N.B. The new bridge will span the river a little farther up than does the present one.

Howick, Que.—Tenders will be received up till December 10th for the construction of about 5 miles of macadamized road in the Parish of Tres St. Sacrament, County of Chateauguay, Que. Plans and specifications may be obtained from D. R. Hay, Secretary-Treasurer, Municipal Council, Howick, Que.

Montreal, Que.—Delay in the matter of settling the underground railway question in Montreal is inevitable, due to engineering and financial problems which must first be solved. It must be ascertained whether a subway under St. Catherine Street can pass the C.N.R. tunnel, which passes under that street at McGill College Avenue. In the case of the Tramway Company's offer, no idea of the cost of the proposed subways can be made until it is known whether the company proposes to build two or four-track subways. There is also the question of the depth of the tunnels to be considered, the steep hills and grades to be encountered. Negotiations will doubtless extend over several months.

Ottawa, Ont.—At a special meeting of the Board of Control it has been settled that the new Billings' bridge will not be a temporary construction, but that traffic will be diverted by way of Hurdman's bridge until the completion of the permanent structure. A rapid start on the work has been urged, which, according to City Engineer Currie's plans, will be 350 feet long and 60 feet wide, with four concrete piers and steel superstructure, and will cost $60,000. Tenders will be called for as soon as possible.

Ottawa, Ont.—The selection of a site for a new bridge over the Rideau Canal has been left to the city engineer. The residents across the canal are endeavoring to have a temporary bridge erected for the winter.

+—**Ottawa, Ont.**—The contract has been awarded by the Dominion Government cabinet council to the CANADIAN DREDGING AND CONSTRUCTION COMPANY for four bridges in Districts C and D of the Transcontinental Railway, at a cost of $9,469.

St. Catharines, Ont.—The alternative bridge plan at St. Paul Street has been reported upon by the city engineer to the civic council and as a result has been abandoned as a means of improvement. The council has resolved to engage the services of a consulting engineer to prepare a report on other routes in an endeavor to arrive at the most feasible solution of the problem.

Toronto, Ont.—The Street Improvement Committee, a sub-committee of the Civic Works Committee, has decided to ask the city council to approve plans for the extension of several streets in Wards Six and Seven. With regard to the extension of Campbell Avenue south to Bloor Street in Ward Six, while recognizing that it was desirable, the committee decided the present time was inopportune.

+—**Vancouver, B.C.**—The contract for building the passenger subway to the North Vancouver ferry wharf has been practically awarded to the M. P. COTTON COMPANY by the civic bridges and railways committee, its tender of $30,105 being the lowest of fourteen submitted to the committee. Before being actually awarded, however, the city engineer will make a report to be read before the City Council. The committee will proceed with the subway, and will install pumps to countervent the wet weather.

+—**Vancouver, B.C.**—The city council has awarded the contract for the North Vancouver pedestrian subway to the M. P. COTTON COMPANY, its tender of $30,105 being the lowest received. The council adopted the city engineer's recommendation that excavation work be delayed until spring

When designing

structures do you pay sufficient attention to the various matters that govern insurance ratings?

Not only can you add greatly to the fireproofness of buildings by adopting our suggestions, but it is very likely that you can do so without the improvements costing anything ultimately. They will be paid for by the lower insurance rates.

Correspondence solicited. We have a staff of engineers and inspectors trained in this highly specialized line. Make use of our services

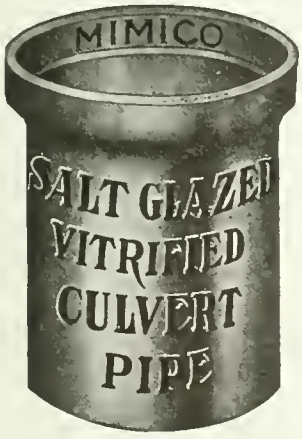
Sewers must carry the sewage quickly and surely to the distant point of disposal.



Therefore they must not only be laid in a proper gradient, but they must also be of a smooth material that will not cause delays in the flow of the sewage. Smooth, round, perfect, salt-glazed vitrified pipe, without blisters or scales and without cracks—in short, MIMICO PIPE—is absolutely required for a perfect sewer. It will pay you to get in touch with us.

Fourth Revised and Enlarged Edition

A Treatise on Wooden Trestle Bridges

And Their Concrete Substitutes. According to the Present Practice on American Railroads. By WOLCOTT C. FOSTER. 4to, xix+440 pages, 180 figures, 76 full-page plates. Cloth, $5.00 net.

In revising this book the author has brought the subject-matter down to the present time. New matter has been added to every chapter. Various standards and rules of practice adopted by the different associations have been included in their proper places. Two new chapters, one giving a short outline of timber preservation and one on concrete trestles, have been added.

High Masonry Dam Design

By CHARLES E. MORRISON, C.E., Ph.D., formerly Instructor in Civil Engineering at Columbia University, and ORRIN L. BRODIE, C.E., Assistant Designing Engineer, New York Board of Water Supply. 8vo, iv+103 pages, 19 figures. Cloth, $1.50 net.

In this volume the computations for the design of a high masonry dam are appended to facilitate the ready comprehension and application of the formulæ.

The Elements of Specification Writing

A Text-book for Students in Civil Engineering. By RICHARD SHELTON KIRBY, C.E., Professor of Civil Engineering, Pennsylvania College; Member of the Society for the Promotion of Engineering Education. 8vo, vii+125 pages. Cloth $1.25 net.

A text-book on the art of specification writing. While intended primarily for the classroom, it will also prove of value to the young engineer in practice. Includes the fundamentals of a contract, particularly of a construction contract with its attendant plans and specifications, concisely brought out.

Third Edition, Re-written

Elements of Water Bacteriology

With Special Reference to Sanitary Water Analysis By SAMUEL CATE PRESCOTT, Associate Professor of Industrial Microbiology at the Massachusetts Institute of Technology, and CHARLES-EDWARD AMORY WINSLOW, Associate Professor of Biology, College of the City of New York, and Curator of Public Health, American Museum of Natural history, New York. 8vo, xiv+318 pages. Cloth, $1.75 net.

This edition contains many important changes and additions. A new chapter on the application of bacteriology to the sanitary study of shellfish has been added, due to the growing importance of this subject.

to avoid the wet weather and to allow the C.P.R. to drive piles for certain tracks.

Victoria, B.C.—The report of the provincial engineer, Mr. Griffiths, following his investigation of the project and estimate of construction of the Second Narrows Bridge, is at present under consideration.

Victoria, B.C.—Further conference is being held on the question of the Johnson Street bridge with the hope of getting the project sufficiently settled and advanced to submit the necessary by-law to the city council early next month, and to ratepayers, at the annual January elections. It will be the largest money by-law on the list, if sufficiently advanced to be included.

Victoria, B.C.—With regard to the new Johnson Street bridge, the Inner Harbor Association favors the increase in the grade of the approach, and suggests provision to give a clear headway under the central span of 36 feet of high water. The attitude of the association is to be communicated to the city council, and attention is to be drawn further to the fact that it is about 400 feet from Store Street to the movable span of the bridge, and that in this distance a rise of about 18 feet would have to be obtained to securet a clear headway of 36 feet at high water. This would give a grade of four and a half per cent., which would be easier than that at Portland, A general conference is to be held of government, railway, and city officials; and it is expected that some progress will be made in advancing this important work.

Victoria, B.C.—The Hon. Thomas Taylor, provincial minister of public works, has announced the plans for the new government bridge to span the Pitt River at the Dewdney trunk road are sufficiently complete to admit of the call for tenders at an early date. Work is expected to be well under way next spring; though, due to the difficulty of the work, the erection can hardly be completed much before 1915. The bridge when completed will cost between $400,000 and $450,000, and is to provide for railway traffic as well as vehicular and pedestrian traffic.

Victoria, B.C.—In the recommendations of the finance committee of the city council, still to be considered by the council, is a suggestion for an appropriation to start the new railway bridge across the street at Hereward road. This is the last trestle on the Esquimalt and Nanaimo Railway in Victoria West before it reaches the boundary at Dominion road.

Winnipeg, Man.—Owing to the adjournment of the regular meeting of the city council, consequent on the sudden death of Assistant Engineer R. D. Willson, no definite action was taken at the city hall last night on the Talbot Avenue sub way matter.

Winnipeg, Man.—The city council has passed the following resolution concerning the construction of a subway at Talbot Avenue: "That an appropriation, equalling the amount which the Board of Railway Commissioners for Canada shall fix as the city's share of the cost of constructing a subway at Talbot Avenue, under the Canadian Pacific Railway tracks, be made, and authority is hereby given that such sum shall be placed to the credit of a fund for the construction of said subway, as shall be determined by the said commission. The Dominion Railway Commission has already been notified of the creation of such a fund by the city and an order compelling the construction of the subway and apportioning the cost is expected within a short space of time.

INDUSTRIAL WORKS.

Ainsworth, B.C.—As a result of representations made by R. F. Green, M.P., and Neil F. Mackay, M.P.P., repairs are to be made by the government to the wharf at Ainsworth in order that it may be in good condition for use until the new wharf, for which tenders have been called, has been built.

+—Ottawa, Ont.—The Dominion government has let the contract for a wharf at Vaill's Point, Grey County, Ont., to W. A. GRIER and A. J. CREIGHTON, of Owen Sound, for $6,983.

+—Ottawa, Ont.—The Dominion government has let the contract for the pier and wharf at Meaford, Ont., to ALEX. GREEN and JOHN WOOLICH, of Owen Sound, for $30,000.

Ottawa, Ont.—It is announced that an exceptionally large number of tenders for Section 5 of the Welland ship canal have been received, and deposit cheques average over $1,000,000. When the awards have been made in the course of a day or two, tenders will be called for the fourth section.

Ottawa, Ont.—Tenders will be received up till December 15th for the construction of a breakwater at Caldwell's Cove, Digby Co., N.S. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

Ottawa, Ont.—Applications have been made to the government by companies interested in the construction of dry docks for legislation increasing the subsidy in respect to such undertakings. The present limit is 3½ per cent. annually, on a maximum of $5,500,000. It is desired that this be increased to 4, 4½ or 5 per cent., it being urged that under present monetary conditions it is very difficult to finance the propositions on the basis of the present subsidy.

+—Ottawa, Ont.—The contract for section 5 of the Welland Ship Canal has been awarded by the Cabinet Council to the CANADIAN DREDGING COMPANY. This section extends from Allenburg to Port Robinson, and will cost $1,945,788.

+—Ottawa, Ont.—The contract has been awarded by the cabinet of the Dominion Government to the MARITIME DREDGING AND CONSTRUCTION COMPANY for extension to wharf and dredging at Chocolate Cove, N.B. The contract price was $26,879.

+—Ottawa, Ont.—The contract has been awarded the MARITIME DREDGING AND CONSTRUCTION COMPANY by the Dominion Government for the construction of a breakwater at Little Dipper Harbor, N.B., at a cost of $10,593.

Ottawa, Ont.—Tenders will be received up till December 15th for the construction of a wharf at Pritchard, Yale District, B.C. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. Signed, R. C. Desrochers, Secretary, Department of Public Works.

+—Ottawa, Ont.—The cabinet has let the contract for the construction of a wharf at Gillies Bay, B.C. The contractors are Hodgson and King, of Vancouver.

+—Ottawa, Ont.—The contract has been awarded the MARITIME DREDGING AND CONSTRUCTION COMPANY for a breakwater at Welsh Cove, Mace's Bay, N.B., at a cost of $11,825.

Sarnia, Ont.—Engineers from the Public Works Department, Ottawa, have been working on an enterprise which affects the entire water front of the St. Clair River. The plan is to fix a limit to the harbor line, and to permanently prohibit the extension of any wharf or pier beyond this line. The work is being done at the request of the Canadian marine interests, and of the United States Lake Carriers' Association, and the survey for the port of Sarnia will be carried from Point Edward to below the town limits, and will include the frontage along the bay shore. It may be that the fixing of the limits will cause a modification of the plan for a Government pier in Sarnia Bay, but the modification would not be radical.

Vancouver, B.C.—After seven months' delay, the city has received the equivalent of a crown grant, e.g., the sanction of the Deputy-Minister of Justice at Ottawa, for the use of the bed of False Creek for 300 feet west from Main Street, which is to be enclosed by a sea wall to be built by the C.N.R. Company. A committee has been engaged to form plans for the sea wall, which will take the form of a wharf with piers probably extending at right angles. Chairman Carter-Cotton has asked on behalf of the Harbor Commission, that two slips be provided at the retaining wall.

MISCELLANEOUS.

Grand Forks, B.C.—T. M. Sutherland, who is in charge of the forestry department of the Kootenays and Boundary, has instructed his men to proceed with the construction of the telephone line up the north fork of the Kettle River as far as Franklin camp. It is the intention of the department to have the line extended into the city and connected up with the local telephone exchange.

Montreal, Que.—Tenders will be received up till December 10th for the construction of two steel wharf transit sheds, Sections 24 and 25, Harbor of Montreal. Plans and specifications may be obtained from Mr. F. W. Cowie, Chief

TRANSPORTATION BUILDING — MONTREAL

Engineer, Montreal, Que. Signed, David Seath, Secretary, 57 Common Street, Montreal.

▲—**Ottawa, Ont.**—Tenders will be received up till December 11th for the roofing of St. Gabriel shed No. 1, Ottawa Street, Lachine Canal. Plans and specifications may be obtained from the office of the Chief Engineer, Department of Railways and Canals Ottawa, Ont. Signed, L. K. Jones, Esq., Ass't Deputy Minister and Secretary, Department of Railways and Canals.

Ottawa, Ont.—Tenders will be received up till January 8th for the construction of a steel twin-screw ice-breaking steamer to be delivered at the King's wharf in Quebec City. Plans and specifications may be obtained from the office of the Purchasing Agent, Marine and Fisheries Department, Ottawa, Ont. Signed, Alex. Johnston, Esq., Deputy Minister of Marine and Fisheries.

Ottawa, Ont.—Tenders are expected to be called for very shortly for the new government ice-breaker which is to be built for the St. Lawrence next year. Plans and specifications will be accessible at the Montreal offices of the marine department in the Shaughnessy building. They call for an 8,000-ton twin-screw steel ship, 292 feet long, 56 feet 9 inches wide and 32 feet deep. The crew will number 90, and with the exception of the 10,000-ton Russian steamer Hermak, the new boat will be the largest in the world.

Ottawa, Ont.—On the 18th of April, 1913, the Bell Telephone Company will open the Carling exchange, now under construction in Ottawa. This will improve the service throughout the city, and will accommodate about 2,500 subscribers when it is opened.

✚—**Ottawa, Ont.**—The Dominion Government has awarded the contract for addition and alterations to Orillia public buildings to C. WEBB & SON, at a cost of $31,485.

Port Arthur, Ont.—The Miles Car and Manufacturing Company of Cleveland, Ohio, may establish a plant at either Port Arthur or Fort William. The company has written Manager Robinson, of the local railway, concerning facilities for extending its business in Canada and at this centre.

Quebec, Que.—The plans for the new Union Station at Quebec have been enlarged, the Government having reconsidered its ideas as to the nature and extent of the joint occupancy.

Steveston, Lulu Island, B.C.—Reeve Bridge has stated that he has received assurance that the Columbia Cold Storage Company will construct at once its building and equipment at a cost of over $170,000, and to be completed if possible by next April. Already arrangements have been made for the construction of a spur from the British Columbia Electric Railway to serve the plant and warehouse.

Sydney, N.B.—Mr. Gillies, president of the city board of trade, has written to the Hon. J. D. Hazen, Minister of Marine and Fisheries, on behalf of the board, to request the government to act in regard to keeping open from Jan. 20th to April 1st, the Sydney harbor. If an ice-breaker were in operation during this period, there would result great remunerative advantage to the city.

Vancouver, B.C.—Tenders have been called for by the Great Northern Railway Company for the excavation for the site of their new passenger depot to be built in this city. It is expected that the work will commence shortly. The earth removed will be used to fill in between the piling on the city's harbor work.

Vancouver, B.C.—The only information given by Mr. J. J. Hill and Mr. Louis W. Hill, while in Vancouver, concerning the terminal improvement schemes of the G.N.R., was that plans for the new joint passenger depot for the G.N.R. and N.P.R. lines at False Creek are being prepared.

CURRENT NEWS.

Fredericton, N.B.—The Dominion Bridge Company's erecting crew are starting to place the superstructures on the steel bridges on the Kettle Valley road. They are starting work at Centreville and will work south to Gagetown as rapidly as possible.

Fredericton, N. B.—The Foundations, Limited, have completed their work at the Highway Bridge and the greater part of their plant has already been shipped to Montreal.

Fredericton, N.B.—Messrs. A. E. Trites and Son, the construction contractors on the Gibson and Minto Railway, have completed the balasting work on the railway. The entire work is now practically complete.

Hanna, Alta.—The Alberta Pacific Elevator Company, Hanna, have their new house here well on towards completion. The cribbing has all been completed, the roof is on and the interior work will be completed with all haste. It is hoped that it will soon be ready for business as the National Elevator here is overtaxed.

London, Ont.—City Engineer W. N. Ashplant is rushing the contractors for the Wharncliffe bridge at their top speed, and it is expected that the concrete work will be completed early in December at the latest. The piling on the West London pier has already been driven, and concrete work must be stopped when frost sets in. But piling on the South London pier for the new bridge will continue during the winter; since the South London abutment work is on the high side of the river, and is not in danger of flooding.

Moose Jaw, Sask.—A start has been made by J. D. Wheeler, grading contractor, on the site of the temporary freight and station terminals of the Grand Trunk Pacific on Main Street North, and the work is to be rushed with all possible speed to completion. There is considerable cutting to be done, and also a large fill where the spur track will leave the main line.

Newcastle, N.B.—Work on the new wireless station here is progressing rapidly. The main steel tower has been commenced, the remainder of the steel work for it having arrived recently from England. Four of the six wooden towers are now over two hundred feet high and rapidly nearing completion, as is the power-house, which is being built of concrete and steel.

New Liskeard, Ont.—Good progress is being made upon the laying of water mains from the Dunn Springs to connect with New Liskeard's water supply. Mr. Hiram Proctor is the engineer in charge.

New Westminster, B.C.—Work has been begun filling in the piling built off Eighth Street for the new harbor work. The dredge John A. Lee is anchored off the head of Lulu Island and has begun loading the scows with the sand and silt which will be employed in the filling.

Penticton, N.B.—On the Kettle Valley Railway, on the west fork of Kettle River, between Beaverdell and the summit, splendid progress is being made. The grade is already finished to the summit, and the steel is within ten miles. The work on the tunnel on the Penticton side of the summit is progressing satisfactorily.

Port Arthur, Ont.—The double track on the C.P.R. between Port Arthur and Navilus on the eastern division has been completed, the connecting link being made by the finishing of construction on Current River bridge.

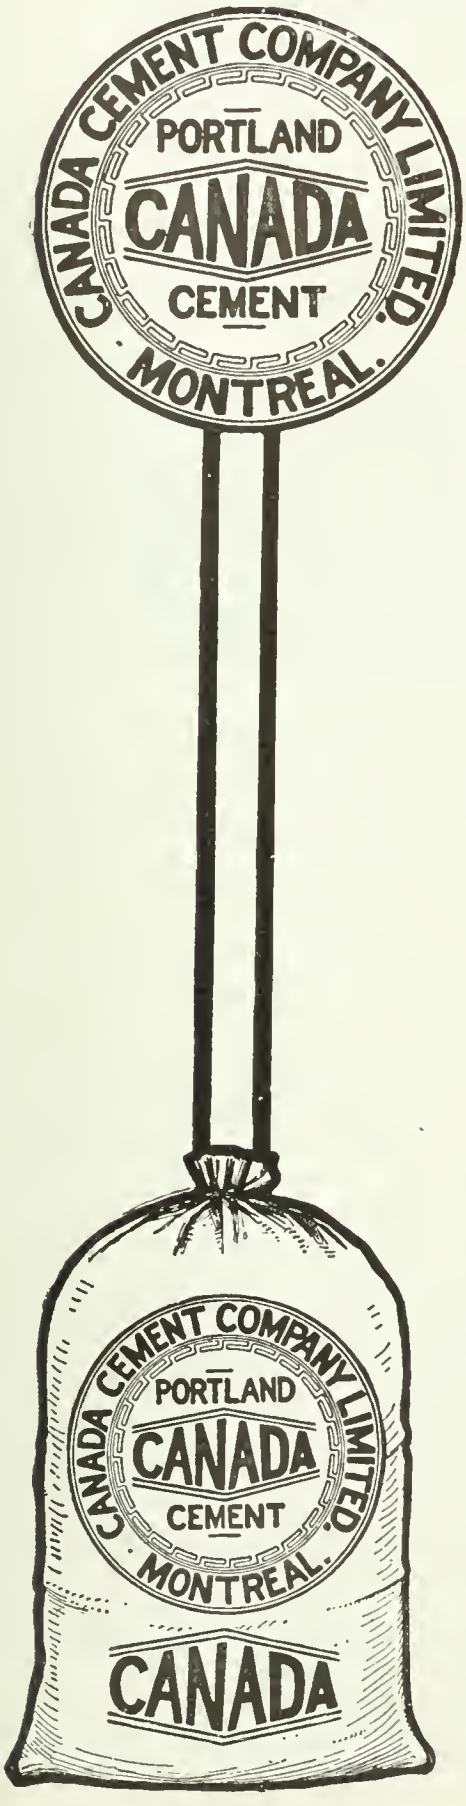
Sarnia, Ont.—Surveyors for the Government are now in Sarnia making an extensive survey of the proposed new harbor. The work will be carried on through the winter until it is completed.

Smithers, B.C.—What is probably the highest suspension bridge in the world has just been completed across the Bulkley River at Hagwilgate. It is 250 feet above the river, and is 600 feet in length. Moreover, it is one of the biggest single span suspension bridges in the world. Its one span being 451 feet long. Aside from the work of the Grand Trunk Pacific, this bridge is the biggest engineering project ever undertaken in the Northern Interior of British Columbia. It was built by George Cradock and Company, of Wakefield, England, and is the largest single bridge contract ever undertaken by that firm. The structure is of a special stiffened type, suspended from catenaries of locked coil cables which do not rotate or lengthen. The bridge is as rigid as it is possible to make it. In addition to its guaranteed carrying capacity allowance is made for meeting any extra strains that may be put upon it such as wind or other stresses.

St. Catharines, Ont.—The civic council has decided to stop all work on the Ontario Street bridge until spring.

St. John, N.B.—Mr. Josephy McVey, of McVey and Son, has stated that the company will complete the sub-structure of the new bridge at the Falls on schedule time, so that the Dominion Bridge Company may commence work on the superstructure. Mr. McVey's firm has already blasted between 4 and 5 thousand cubic feet of rock on the Carleton side of the Falls to prepare for the masonry work to support the spandial arch. His company will build the retaining wall, and also

PERMANENCE—



an ideal that is now attainable

THE superiority of concrete over all other materials for the buildin of permanent structures is now generally adm tted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

CANADA CEMENT COMPANY

Limited

MONTREAL

Sales Offices at

MONTREAL TORONTO WINNIPEG CALGARY

sink four anchor holes, two on each side of the Falls, each 30 feet deep in the ledge, for the Dominion Bridge Company.

Sydney, N.B.—An extension to Sydney's "White Way" is now on foot, and every effort is being made to have the work completed before Christmas.

Vancouver, B.C.—Pouring of concrete has begun on the Main Street end of the Georgia-Harris bridge, and the contractors are laying about 400 cubic yards a day, working two shifts of eight hours each. There are about 2,500 cubic yards to lay in this section, but Mr. A. P. Hueckel, engineer in charge, expects the work to take about ten days in all. The retaining wall at Georgia Street is finished as well as the foundations for the pillars across the C.P.R. yards to False Creek. The contractors expect to have the structural steel for this portion of the bridge partly on hand about the beginning of next month. Depending on what pieces are shipped first, they will begin the steel fabric at once, working right through the winter.

Vancouver, B.C.—The harbor work is once more in operation, and filling in back of the dock already built is in progress. The dredge has been anchored at the head of Lulu Island and scoops up sand and silt from the river bed to fill the scows. Later this will be covered with rock and gravel. Pile-driving will be resumed shortly.

Vegreville, Alta.—The town authorities have succeeded in disposing of $30,000 worth of debentures. Work has accordingly begun toward connecting the unfinished water main with the water tank, which is nearing completion, and also toward piping natural gas from the town well to light the streets. The present electric light plant is unable to keep pace with the town's growth.

Victoria, B.C.—Premier McBride has announced that the various proposals respecting the construction of Second Narrows bridge will be taken up by the provincial executive. He has received a communication from the directors of the Burrard Inlet Tunnel and Bridge Company, asking for an early statement as to the government's intentions in the matter. The government, as has already been announced, has been asked to assume control of the project. Sir Richard McBride discussed the matter with Sir John Wolfe Barry, bridge engineer, while in England, and has one or two schemes to lay before the provincial cabinet.

PATENTS.

The following is a list of patents recently issued through the agency of Messrs. Ridout & Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained:—

Canada.—Leslie Bradford, separation of metallic sulphides from gangue; Hugh Arthur Thomson, ozone producers, with treatment bottle attachments, for the destruction of tubercule bacilli; Chas. C. Wakefield, intermittent driving mechanism for lubricators; Harry G. Akers and Alex. Bonnington, fixation of nitrogen. James M. Wilson, rotary pumps and motors; Gustaf E. Ohrn, methods and apparatus for concentrating ore.

TRADE ENQUIRIES.

The following enquiries relating to Canadian trade have been received: 1786.—Firm of undoubted standing in Nurnberg, Germany, having extensive connection in Europe, would undertake to represent a first-class Canadian exporter of asbestos, mica and mineral products. 1709.—Electrical and Mechanical Engineer, resident in Toronto, having undertaken manufacturers' agency, contemplates three or four months' tour through Great Britain, and desires to communicate with reliable Canadian manufacturers with a view to introducing their goods. Enquirer is familiar with machinery generally, but will handle any manufactured line. 1808.—Samples and prices of wire are asked for by a Cape Town firm of importers. 1821.—Samples and prices of wire are asked for by a South African importer.

The names of the firms making these enquiries, with their addresses, can be obtained upon application to: "The Enquiries Branch, the Department of Trade and Commerce, Ottawa," or the Secretary of the Canadian Manufacturers' Association, Toronto, or the Secretary of the Board of Trade at London, Toronto, Brandon, Halifax, Montreal, St. John, Sherbrooke, Vancouver, Victoria, Winnipeg, Calgary, and Chambre de Commerce du District du Montreal.

NEW INCORPORATIONS.

Medicine Hat, Alta.—The Redcliffe Gas and Oil Company, Limited, $300,000.

Edmonton, Alta.—Coalondyke Coal Mining Company, Limited, $200,000.

Lacombe, Alta.—The Middle West Construction Company, Limited, $50,000.

Prince Rupert, B.C.—North Pacific Iron Mines, Limited, $600,000.

Fort Steele, B.C.—Fort Steele Waterworks Company, Limited, $20,000.

Swift Current, Sask.—The Swift Current Concrete Products Company, Limited, $50,000.

Vancouver, B.C.—Consolidated Contractors, Limited, $250,000. Maclennan Construction Company, Limited, $25,000.

Toronto, Ont.—Blodgett Re-Inforced Safety Tube Company, Limited, $100,000. W. H. Cook, G. B. Jackson, A. I. Shortt.

Windsor, Ont.—McNaughton-McKay Electric Company, Limited, $40,000. A. McKay, J. R. McNaughton, F. H. Boyer.

Montreal, Que.—Electrical Properties, Limited, $1,000,000. C. A. Pope, G. Barclay, W. B. Scott. White Smelting and Refining Works, Limited, $20,000. J. W. Richards, J. A. T. Richards, P. du H. Richards.

The Independent Oil Company, Limited, $250,000 Standard Oil Fields of Alberta, Limited, $650,000. United Oil of Alberta, Limited, $2,500,000. Sentinel Oil Company, Limited, $150,000. Great Northern Oil and Development Company, Limited, $200,000. The Herron Elder Gas and Oil Development Company, Limited, $1,500,000. The Pacific Oil and Refining Company, Limited, $500,000. Mountain House Oil Company, Limited, $100,000. The Deep-Well Oil and Development Company, Limited, $200,000. The Western Pacific Oil Company, Limited, $250,000. Alberta Hydro-Electric Company, Limited, $1,000,000.

MONTREAL MARKET LETTER

Montreal, November 25th, 1913.

The local iron and steel trade is marking time, and no more. So far as can be learned there is only one branch of the iron and steel industry which is in really comfortable shape just now, and this is the structural steel industry. It is stated that the bridge companies have orders on hand far into the future, and that this is more or less true in respect to all structural steel companies. So far as concerns iron furnaces and rolling mills, these are in rather a doubtful position. Prices are certainly lower than they were some time ago; but it is claimed, on the other hand, that the operating costs have been reduced considerably. Also, the output of some of the concerns has varied noticeably, so that profits are likely to make a better showing than might at first be supposed. Prices of pig iron have not shown any alteration of late; but the basis of quotations will probably be changed next week. Notwithstanding the declines which are taking place from time to time in the United States, the local market would seem to be practically unaffected, quotations being much the same in every instance as heretofore.

Reports from the United States are to the effect that car orders during the past year are likely to be very little more than half those for 1912; and at the moment it does not seem likely that this proportion will be greatly altered by the results of the next month. Orders for all sorts of iron and steel products seem to be falling off, and advices are to the effect that the earnings of the United States Steel Corporation are likely to be considerably affected thereby. In Canada orders for cars have certainly not been coming out as freely as they were a year ago, and at the moment there is every likelihood that some of the car companies will have to slow down during the coming winter.

Sold in Canada by

AZTEC OIL & ASPHALT REFINING CO. of Canada

311 Shaughnessy Bldg., Montreal

Refined by

THE U.S ASPHALT REFINING CO.

AZTEC ASPHALT

Canadian municipal and highway engineers and road contractors should buy Aztec Asphalt on account of the qualities possessed by its bitumen. It is not—like other asphalts—merely "over 99 percent bitumen." Aztec is over 99 percent bitumen of special qualities that make it particularly suitable for Canadian requirements.

AZTEC BITUMEN

is solid, high-grade and best suited to Canadian conditions, because neither frost nor hot weather injures it. Aztec retains its tenacity under all conditions, also resisting all water action.

The extremes of temperature in most Canadian cities make asphalt more of a "problem" for Canadian engineers than it is for engineers in any other part of the Continent. Other asphalts that are entirely successful in South America, Mexico, Europe or in central or southern parts of the United States, might fail in Canada because of the extremes in temperature here.

For Canada asphalt must not only be pure (nearly 100 per cent bitumen) but the bitumen *must retain its tenacity at all temperatures*. In this regard Aztec excels. It is impervious to water, stays malleable even when buried under snow or ice for long periods, does not soften noticeably in summer and has great coherence, resisting wave tendencies.

Aztec is refined near Baltimore, Md., from liquid asphalt, or maltha, imported from Vera Cruz (Mexico), the land of the Aztecs. It is the expert North American labor, added to the high character of the Mexican maltha, that accounts for Aztec's superior qualities.

We would be pleased, upon request, to quote, send samples or mail further literature regarding Aztec Asphalt.

SOLE CANADIAN IMPORTERS

TENDERS CALLED FOR

TENDERS FOR A COMPLETE MECHANICAL FILTRATION PLANT.

BOILERS, STEAM TURBO-GENERATOR PLANT AND ALL APPURTENANCES.

Tenders will be received by registered post only addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on

Tuesday, January 20th, 1914,

for the installation of a complete Mechanical Filtration Plant, Boilers, Steam Turbo-generator Plant and all appurtenances at Toronto Island.

Specifications and Tender forms may be obtained upon application at the office of Mr. James Milne, Mechanical and Electrical Engineer, Department of Works, City Hall, Toronto.

Envelopes containing tenders must be plainly marked on the outside as to contents.

The usual conditions relating to tendering as prescribed by City by-law must be strictly complied with, or the tenders may be declared informal.

Tenderers shall submit with their tenders the names of two personal sureties approved by the City Treasurer, or, in lieu thereof, the bond of a guarantee company approved as aforesaid.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

City Hall, Toronto, November 25th, 1913.

DEPARTMENT OF RAILWAYS AND CANALS.

LACHINE CANAL.

NOTICE TO CONTRACTORS.

ROOFING ST. GABRIEL SHED No. 1.

Sealed tenders, addressed to the undersigned and endorsed "Tender for Roofing of St. Gabriel Shed No. 1, Ottawa Street, Lachine Canal," will be received at this office till **12 o'clock noon, Thursday, December 11th, 1913.**

Plans, specifications and form of contract to be entered into can be seen on or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer of the Quebec Canals, New Birks Building, Montreal, Que.

An accepted bank cheque on a chartered bank of Canada for the sum of $500.00 made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,
L. K. JONES,
Asst. Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 22nd November, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it. 51421.

BURRARD PENINSULA JOINT SEWERAGE BOARD.

TRUNK SEWERS. CONTRACT No. 1.

Sealed tenders for the construction of Trunk Sewers endorsed as above and addressed to the undersigned will be received until **2 o'clock p.m., December 1st,** at the offices of the Board 514/518 Birks' Building, Vancouver.

The proposed works comprise approximately ten thousand (10,000) feet of concrete sewer, with appurtenances, varying in diameter from 6 ft. 6 in. to 4 ft., including all work and the finishing of all material. Alternative tenders for monolithic and pipe sewers will be considered.

Plans, specifications, forms of tender and contract can be seen at the offices of the Board on and after November 20th, and copies of same may be obtained from A. D. Creer, Engineer to the Board, on payment of a sum of $50.00 (by marked cheque), which will be refunded on the return of all plans and documents supplied.

No tender will be considered unless accompanied by a certified cheque upon a Vancouver branch of a Chartered Bank, payable to the order of the Board, for a sum equal to 5 per cent. of the amount of the contract. The cheques of unsuccessful tenderers will be refunded to them upon the contract being awarded, and the cheque of successful tenderer will be returned upon execution and delivery of contract and bond for due performance thereof.

The right to reject any or all tenders is reserved, and no tender will be considered which is not in conformity with the specifications.

By order of the Board,
G. W. PHIPPS,
Secretary.

514 Birks' Building, Vancouver, B.C.

TENDERS FOR MACHINERY AND EQUIPMENT.

Tenders will be received by the Bowness Improvement Company at their offices, 202 Eighth Avenue West, Calgary, Alberta, until 5 p.m., December 31, 1913, for the following machinery and equipment:—

"L." One 200 k.w. Traction Motor Generator.
"M." One four panel Switch Board.
"N." One 250 k.v.a. Generator.
"O." One Vertical Single Acting Multi-Cylinder Gas Engine.

Bidders must enclose certified cheque in the amount of 5 per cent. of their tenders. Cheques of unsuccessful tenderers will be returned immediately after contracts are awarded. Specifications may be obtained from the engineer, and may be seen in the offices of *The Canadian Engineer*, 820 Union Bank Building, Winnipeg, 62 Church Street, Toronto and 628 Transportation Building, Montreal.

The lowest or any tender not necessarily accepted.

T. L. TURNBULL,
Consulting Engineer,
202 Eighth Avenue West,
Calgary, Alberta.

TENDERS FOR PUMPING PLANT, ETC.

Sealed tenders will be received by C. F. Monroe, Township Clerk, for a pumping plant for use in the new Waterworks System of the Township of Stamford, County of Welland. The source of water supply being one or more 8-inch wells.

Tenders will also be received for Wrought Iron, Cast Iron and Steel pipes, in sizes from ¾ inch to 10 inch, with valves, Fire Hydrants, etc.

Quantities and other information may be obtained from J. C. Gardner, Township Engineer, Niagara Falls, Ont.

Tenders must be in the hands of the Township Clerk not later than 2 o'clock p.m., Monday, December 1st, 1913. The lowest or any tender not necessarily accepted.

C. F. MONROE,
Township Clerk, South End P.O.

Steel Bridge For Sale

An excellent opportunity is offered to bridge constructors, contractors, etc., for obtaining a substantial, well-built steel bridge ready for immediate delivery at a moderate price. This bridge was formerly in use by the Canadian Pacific Railway over the St. Lawrence River at Lachine, P.Q., and was recently replaced by a double track structure. It is in excellent condition.

CITY OF MOOSE JAW.

WANTED—CITY ENGINEER.

Applications addressed to the undersigned will be received for the position of City Engineer for the city of Moose Jaw.

Apply, giving experience, reference and salary required.

E. B. BONNELL,
City Clerk.

Dated at Moose Jaw this 12th day of November, 1913.

FIRM OF PUBLIC WORKS CONTRACTORS require the services of a first-class civil engineer to take charge of engineering department on large canal contract in Canada. Must be thoroughly experienced in this particular class of work. State experience, age, salary required, and give references. All applications will be treated in strict confidence. Apply Box 178, *The Canadian Engineer*, Toronto.

CHIEF ENGINEER.—Good opportunity is offered to an experienced engineer to connect with an established Consulting, Engineering and Construction Corporation based on co-operative plan; offices in Cleveland, Detroit, Buffalo, and New York City. The position requires a man to take complete charge of the mechanical, electrical, and civil engineering departments. Highest references and $1,500 investment required. Contract with salary commission and expenses guaranteed. Address Box 184, *Canadian Engineer*, Toronto.

Positions Wanted

Advertisements under this heading one cent per word per insertion. Minimum charge fifty cents per insertion.

ENGINEER—Position in Toronto or vicinity as assistant to Executive Head or Chief Engineer. Experience: Two years' University Engineering Course, six years' office and eight years' Mechanical and Civil Engineering. Familiar with Reinforced Concrete and Structural Work. Canadian. Age 32. Box 180, *Canadian Engineer*, Toronto.

GRADUATE SWISS CIVIL ENGINEER, with experience, wants appointment in Reinforced Concrete firm. Also seeks work for spare time. Preferred difficult calculations for reinforced concrete work, statically indeterminate systems. Please address Box 182, *Canadian Engineer*, Montreal.

Condensed Advts.

PATENT NOTICE.—Any one desiring to obtain the invention covered by Canadian Patent No. 122,662, granted on December 14th, 1909, to Harry Arthur Westmoreland, of London, England, for Dropper and Standard, may do so upon application to the undersigned, who are prepared to supply all reasonable demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh & Smart, 53 Queen Street, Ottawa, Canada. Russel S. Smart, resident.

PATENT NOTICE.—Any one desiring to obtain the invention covered by Canadian Patent No. 137,430, granted on December 19th, 1911, to Seth W. Eddy, of Lincoln, Nebraska, for Mirror, may do so upon application to the undersigned, who are prepared to supply all reasonable demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh & Company, 53 Queen Street, Ottawa, Canada. Russel S. Smart, resident.

PATENT NOTICE.—Any one desiring to obtain the invention covered by Canadian Patent No. 120,660, granted on December 6th, 1910, to Chas. Glaser and George J. Muller, of Baltimore, Md., for Process of Refining Salt, may do so upon application to the undersigned, who are prepared to supply all reasonable demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh & Smart, 53 Queen Street, Ottawa, Canada. Russel S. Smart, resident.

NEW INCORPORATIONS.

Montreal, Que.—Armstrong, Whitworth, of Canada, Limited, $2,000,000. Sir E. P. Cranwill, Right Hon. Sir George H. Murray, S. W. A. Noble. Roger Miller and Company, (P.E.I.), Limited, $200,000. W. R. L. Shanks, F. G. Bush, G. R. Drennan. British Manufacturers' Association of Canada, Limited, $10,000. L. A. David, L. J. Maurice, Dugas, L. E. A. d'Argy-Mailhoot.

Calgary, Alta.—The Shale Brick Company, Limited, $100,000. Western Prairies Oil Development Company, Limited, $250,000. Lucky Mary Oil and Natural Gas Company, Limited, $200,000. Huron and Bruce Oil and Natural Gas Company, Limited, $200,000. The Scottish Oil Company, Limited, $10,000. Marine Oil Products, Limited, $500,000. The Golden West Oil and Gas Syndicate, Limited, $500,000 Great West Oil Lands, Limited, $250,000. Rabbit Foot Oi and Gas Company, Limited, $500,000.

Manufacturing 48" Pipe at Berlin, Ontario, Canada.

MERIWETHER SYSTEM

CONTINUOUS RE-INFORCED CONCRETE PIPE

PATENTED

LOCK JOINT PIPE COVERS NORTH AMERICA

Sewage flowing through Lock Joint Pipe reaches the Atlantic Ocean, Pacific Ocean, Gulf of Mexico, Hudson's Bay and the Great Lakes.

Lock Joint Pipe is in use for sewers and water conduits in the following States: Connecticut, Delaware, Florida, Georgia, Illinois, Indiana, Kansas, Kentucky, Maryland, Massachusetts, Michigan, Missouri, New Hampshire, New Jersey, New York, Ohio, Oregon, Pennsylvania, South Carolina, Texas, Virginia, Washington.

The following Provinces of Canada: Quebec, Ontario, Saskatchewan, Alberta and British Columbia.

And in the Island of Cuba.

The Lock Joint Pipe Company is the largest manufacturer of reinforced concrete pipe in the world.

LOCK JOINT PIPE CO.

QUEBEC and ONTARIO—Francis Hankin & Co., 202 Coristine Bldg., Montreal; 117 Mail Bldg., Toronto.
MANITOBA, SASKATCHEWAN and ALBERTA—Canadian Lock Joint Pipe Co., Ltd., Regina, Sask.
BRITISH COLUMBIA—Pacific Lock Joint Pipe Co., 1005 A St., Tacoma, Wash.; Globe Bldg., Seattle, Wash.

MARKET CONDITIONS

Montreal, November 24th, 1913.

Bar Iron and Steel—Trade is reported active. Bar iron, $2.05 per 100 pounds; best refined horseshoe, $2.30; forged iron $2.20; mild steel, $2.15; sleigh shoe steel, $2.15 for 1 x ⅜ base; tire steel, $2.25 for 1 x ⅜ base; toe caulk steel $3; machine steel, iron finish, $2.25.

Cement—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1 40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in. $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3 45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1-in., $3.05.

Explosives and Accessories—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25 lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3 50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4.30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $21.75 per ton; selected Summerlee, $21 25; soft Summerlee, $20.75 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19 to $19.50 per ton, on track.

Lath—See Lumber, etc.

Lumber, etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph poles: seven-inch top, cedar poles, 25-ft. poles, $2, each; 30 ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce 4-ft. x 1½ in., mill run, $3 to $3.25; pine 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2 10; XX, $2.40; XXX, $2.80.

Pipe—Cast Iron—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe—Wrought and Galvanized—Demand is fair and the market steady: —¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent. off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. off for galvanized: 3½-inch $95 4-inch, $1.08.

Toronto, November 26th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes—Orders continue active. Lap-welded, steel, 1¾-inch, 10c. 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $14 to $15 per M., three grades.

Broken Stone—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washaco, $2.50 per ton for small, and $1.15 for large, freight to Toronto 60 cents.

Cement—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks, 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c to 24½c. per lb.

Detonator Caps—75c. and $1 per 100; case lots, 5,000, 20 per cent. off.

Dynamite—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents per pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cents.

Fuses—Electric Blasting—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2 in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain—¼-inch, $5.75; 5-16-inch, $5.15; ¾-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3 55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanized Pipe, ¼-inch, $2.86; ⅜-inch, $2.86; ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead—Firmer, $5.25 to $5.50.

Pig Iron—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green $8, with a prospect of advance. Dealers are fairly busy.

Sand—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0 25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes 9 inches and under, or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels—Active—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2 75 to $3 per 100 lbs. Extra for smaller sizes of angles and tees.

Sheet Copper—22c. per lb.

Sheet Steel—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized—Apollo Brand—Sheets, 6 or 8 feet long, 30 or 36 inches wide: 10-gauge, $3; 12-14-gauge, $3; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 lbs. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates—3-16 inch, $2.40 per 100 lbs.

Zinc—Spelter—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, November 25th, 1913.

Anvils—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¾ to 10¾c., anvil and vise combined, each $5.50.

Bar Iron—$2.50 base.

Bars—Crow, $4.50 per 100 pounds.

Beams and Channels—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick—Kiln run per M, $13; sewer pipe per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland—$2.40 to $2.50 per barrel.

Chain—Coil, 3 16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7.16, $4.75; ½, $4.50, 9-16, $4.50; ⅝, $4.40; ¾ $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie cut, 70 and 10 per cent.

Copper—Tinned, boiler, 26½c., planished, 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent. discount.

Dynamite—$11 to $13 per case.

Galvanized Iron—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20 $4; 18 $3.95; 16, $3.90. Queen's Head, 28, $4.80; 26, $4.70; 24, $4.80 22, $4.20; 20, $4.10 per cwt.

Iron—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26 gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English or 30-gauge American, $4.90; 30-gauge American $5.15. Fleur de Lis 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $2.55; ¾-inch, $4; 1-inch, $5.55; 1¼-inch, $7 80; 1½-inch, $9.35, 2-inch, $12.50; galvanized—¼-inch $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled—3-16-in. $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50; cast share steel, $7.50; tire cauld, $4.50 base; tire steel, $3 base; cast tool steel, 1b., 9 to 12½c.

Tool Steel—8½ to 15c. per pound.

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

RAILWAY ECONOMICS

IMPORTANT FACTORS OF THE SUBJECT AS APPLIED MORE PARTICULARLY TO THE RAILWAYS OF CANADA—QUESTIONS AFFECTING LOCATION AND CONSTRUCTION, REVENUE ESTIMATES AND OPERATING COSTS

By J. L. BUSFIELD, B.Sc., A.C.G.I., and W. H. ABBOTT.

RAILWAY economics is a subject to which much attention has been given by railway engineers in recent years. There has been so much construction undertaken by the different railways latterly, that a great amount of data has had to be compiled on the subject of economics. The following table is illustrative of the amount of work that was undertaken and completed by the larger railways in Canada during the year 1912:

Canadian Northern Ontario Railway	195	miles
Canadian Northern Railway	304	"
Canadian Pacific Railway	360	"
Grand Trunk Pacific Railway	608	"
Intercolonial Railway	17	"
Timiskaming and Northern Ontario Railway	30	"
National Transcontinental Railway	358	"

making a total of 1,872 miles of railway in one year.

The problem of transportation in this Dominion is one peculiar to itself, and is made more difficult to deal with on account of the lack of precedent. The conditions cannot well be compared with those in the United States, either as they are now, or as they were when the large transcontinental railways were first developed on the south side of the border, consequently the subject has to be dealt with largely from first principles.

Economics of Location and Construction.—This branch of the subject deals with the relations between the cost of operation and the cost of construction, of any particular section of railway and finding the best location, of that section of railway, which will give the most economical combination of cost and operating expenses and at the same time give the maximum revenue.

There are two classes of location, one being the location of a new line of railway between two points hitherto unconnected, the other being the relocation of an existing piece of railway in order to give more economical and better financial returns.

In the case of an entirely new project it is usual to make a preliminary examination of several different routes and then make a comparison of the following estimated features:—

Probable revenue from each line.
Cost of construction.
Annual traffic—gross tonnage.
Cost of handling such traffic,

and, in addition to these specific items, the effect of future changes in traffic or operating conditions must be considered. This latter is one of the most important items in this country as the railways, more particularly in the Western Provinces, have built and are building lines through practically unsettled districts basing their estimates of the volume of traffic and sources of revenue on the future settlement of the districts adjacent to the railway, the general effect of railway development being to increase the population of that part of the country served by the new line, due to better transportation facilities.

In the case, however, of the relocation of an existing line, besides taking into account the increased efficiency obtainable by the new route or line (which can be computed more accurately than in the case of an entirely new line) allowance has to be made for the possible injury to existing facilities and also for the value of the facilities on the old route which have to be abandoned. In this instance the net income has to be increased to such an extent that a proper return will be obtained on the capital outlay necessary to make the entire change.

Probable Revenue.—There are several methods of estimating the probable revenue or the volume of traffic of a section of proposed railway. The first method is to make a comparison between the whole population of the country and the gross earnings from the operation of all the railways, and then to assume a similar amount per capita for the projected railway. This method is quick and easy, but is very approximate and is really more suitable for a country more developed than Canada, such as the United States, but it is of interest to note that the gross earnings of Canadian railways average about $29 per capita per annum of the whole population of Canada.

A second method is to estimate the probable earnings per mile of railway by a comparison of the earnings per mile of some existing railway or railways similarly situated. The gross earnings per mile is a very variable quantity on different railways and only a very approximate idea can be obtained by this method, but the following table illustrates this more clearly:

TABLE I.

Name of railway.	Gross earnings	Mileage.	Gross earnings per mile.
Intercolonial	$ 11,003,410	1,462.89	$ 7,520
Canadian Northern	20,860,093	4,272.92	4,811
Canadian Northern Ont.	881,953	492.35	1,792
Canadian Northern Que.	1,327,534	369.27	3,597
Canadian Pacific	116,233,812	10,813.70	10,748
Grand Trunk	35,801,975	3,105.82	11,526
Canada Atlantic	2,173,363	459.26	4,766
Halifax & South Western	478,031	378.32	1,264
Timiskaming & Northern Ontario	1,935,421	302.28	6,408

The above railways are selected from those with a greater mileage than 300, but the following table gives similar figures for five of the smaller roads:

TABLE II.

Name of railway.	Gross earnings.	Mileage.	Gross earnings per mile
Algoma Central and Hudson Bay	$545,054	134	$4,067
Bay of Quinte	238,333	89	2,689
Kingston & Pembroke	225,936	109	2,054
Midland Ry. of Manitoba	61,155	98	624
New Brunswick & P.E.I.	37,726	36	1,048

A third method is that of estimating the receipts per head of tributary population. This method is only applicable to those parts of the country where a fairly accurate estimate can be made of the location and magnitude of the population. In Eastern Canada maps can be obtained from the Dominion Government giving the location of all existing railways, highways, buildings, etc., on a scale of one mile per inch. These are a great help in making the population estimate. The proposed road will usually pass through some territories in which it may reckon on obtaining all the traffic. An example of this is where a new railway location is through a valley separated from other railways by intervening hills. The new railway can, in a case like this, assume that it will receive all the traffic from that district. In the case of a new railway passing through a town or village already served by a railway, it cannot expect to obtain half the traffic from that town, but only a proportion of it, depending on the relative importance of the two railways, the transportation facilities to and from the depots, distance from the centre of population, nature of the roads, convenience of the train service and sundry other features.

A fourth method is to make a comparison of the production or the producing character of the country which the railway will tap and that of some territory as nearly similar as possible, and note the revenue of the railway serving that territory. An even better way is to combine the third and fourth methods and compare the new and existing roads by means of their tributary population and by dividing the gross earnings of the existing line by its tributary population, a fair approximation is obtained to the probable gross earnings per capita of tributary population of the proposed route. Allowance has to be made, however, for the different character of the locality served by the existing railway.

The fifth and last method of estimating the probable revenue is probably the most accurate. This method is to make a very close estimate of the amount of business that will be obtained from all the different sources of revenue. This requires a great deal of careful study of all the manufactories, mines, lumber mills, farms and every industry located near the proposed route. It is not difficult to make such an estimate when the railway is being built through a country well populated and not previously served by a railway. But in a great many parts of Canada an estimate of the revenue cannot be based on the existing conditions but only on the future estimated conditions of the country after it has been developed by the railway itself. A factory may also be located in the country to be served and it is usually safe to assume that its business will be increased by the advent of the railway. With regard to farms, an experienced man can make a close estimate of the business to be obtained from them, and the distances their produce will have to be transported to the nearest market. In making this estimate other transportation facilities for the farmers have to be considered. Each proposed station on the route will have to be studied independently and information of each source of revenue gathered together, and also information as to the probable markets for the products at each point. The following table gives the percentages of the different sources of revenue for freight traffic for all the railways in the Dominion of Canada and also for the United States.

TABLE III.

Sources of revenue.	Percentage Canada.	Percentage U.S.
Products of agriculture	19.33	8.13
Products of animals	3.53	2.10
Products of mines	35.20	56.23
Products of forests	15.82	11.67
Manufacturers	18.16	14.42
Merchandise	3.03	3.69
Miscellaneous	4.93	3.72
	100.00	100.00

The relations between freight and passenger earnings varies for different parts of the country, but is approximately the same for all the roads in the same locality. The following table gives the proportions of freight, passenger and other earnings on different Canadian railways:

TABLE IV.

	Freight revenue. %	Passenger revenue. %	Other revenue. %
Alberta Ry. and Irrigation Co.	71	25	4
British Yukon Railway	75	24	1
Intercolonial Railway	65	32	3
Prince Edward Island Railway	48	50	2
Canadian Northern Railway	74	19	7
Can. Northern Ontario Ry.	68	29	3
Can. Northern Quebec Ry.	72	26	2

Quebec Central Railway	68	31	1
Quebec & Lake St. John Ry.	63	34	2
St. Lawrence & Adirondack Ry.	60	39	1
Timiskaming & Nor. Ont. Ry.	56	39	5
Vancouver, Victoria & Eastern Railway	66	32	2

Whatever method is used for estimating the volume of traffic there are always a number of conditions which affect this volume in different ways. For instance, the proximity to the probable source of traffic is a feature to which great attention should be paid. In Eastern Canada where there is keen competition between different railways the locating engineer must subordinate all other requirements to that of locating the road where it will be in a position to obtain the maximum of business. It is always advisable to spend more money on freight and passenger facilities in the cities and towns served by the road, even at the expense of cheaper construction on the line between the cities. There are some good local examples of railways going to great expense to reach the heart of the business districts of the towns and cities where there is or is likely to be competition from other railways. The Campbellford, Lake Ontario & Western

Railway (C.P.R.) has constructed its new line of railway through the busiest part of Trenton, Belleville and other towns of Ontario in order to be in a better position to obtain the local traffic from these towns than the Grand Trunk Railway, which is already established, in many cases, on the outskirts of the towns. Another important instance of this is the construction of the Mount Royal Tunnel by the Canadian Northern Railway at Montreal. This great undertaking will bring the lines of the C.N.R. right into the heart of the hotel and shopping district of the city, to a passenger terminal, and will also give access for the freight traffic to the warehouse and business districts of the city. This question of terminal facilities naturally depends on the limit of capital which may be expended on the terminals without financially wrecking the whole undertaking. The proposal to defer the time of building into the heart of a city is one which should not be considered as it invariably becomes a more and more expensive undertaking as time advances.

Cost of Construction.—In Canada—where there are long stretches of thinly populated country on all transcontinental lines—it was only natural that originally many miles were built of the cheapest construction possible without very much attention being paid to the future requirements, but even though the traffic from these sections is practically nil and they are non-revenue producing, they form links in the chain across the continent and the lines should be built in such a way as to ensure economy of operation for the heavy through traffic. Great sums are now being spent by the Canadian railways improving the grades and alignment on some of the non-revenue producing sections in order to reduce the cost of operation of the whole system.

The type of construction to be adopted naturally will depend entirely on the estimated volume of traffic. If the traffic expected is light, then it would not be a good policy to build the railway at great expense in order to reduce the operating expenses, thus having very high fixed charges, but if the traffic over the road is to be very heavy, then a greater expense of construction per mile would be warranted in order to give a high operating efficiency, i.e., to keep the cost of hauling trains over the road at a minimum. The interest and maintenance charges for a poorly located and constructed road may be $2,500 per mile per annum or more, and the direct cost of hauling one ton over a mile of that road will be nearly a cent. Increasing the efficiency of the location and construction of the railway will necessarily increase the annual interest and maintenance charges, but the cost of hauling each ton will be reduced in greater proportions due to the increase in possible train loads over the better grades of track. There has been, due to these circumstances, a demand for every improvement in location and construction which would enable a railway to conduct transportation more economically.

Having made the preliminary surveys of the alternative routes between any two points, an estimate of the cost of construction of the different lines is made by collecting all the materials of a kind under one head and obtaining unit prices for all the different classifications. A form somewhat similar to the following may well be used for making these preliminary estimates of cost—spaces being left on the right hand side for filling in the actual completed cost of the work, thus serving as a better guide for future estimates.

Item.	Quantity.	Estimated cost. Price.	Subtotal.	Total.	Cost completed. Total.	Price per unit.

The road may be built entirely by contract or by day labor under charge of the engineer or superintendent. The contract method is more usual. The chief engineer will have the entire charge of the work of construction and will, with the assistance of the attorney of the company, after consultation with the officers of the company, draw up all the specifications and contracts for the work. The following table gives the approximate percentages of the different items that go to make up the total cost of building a mile of a standard single-track railway suitable for heavy traffic.

TABLE V.—Percentage of Cost.

1.	Right of way	5·5
2.	Proportionate expense of terminals	13·9
3.	Bridges and culverts	11·0
4.	Grading	33·0
5.	Track laying	19·4
6.	Ballasting	8·4
7.	Fencing	1·4
8.	Telegraph service	0·5
9.	Stations and water supply	3·3
10.	Engineering	1·9
11.	General and legal expenses	1·7
		100.0

Considering these items separately, the cost of right-of-way is one that is naturally extremely variable and will often depend on the publicity given to the whole scheme before the right-of-way agents are able to get the necessary options on the lands. Frequently right-of-way can be obtained cheaper by a carefully studied location. For instance, if the railway is so located that it cuts through farms at right angles to their length the danger is not so great as in the case where the railway locates right down the centre of a long and narrow farm, leaving two even narrower strips on either side. When possible, the best location through cultivated or pasture land is parallel and adjacent to the lot lines.

The second item is one which varies with the nature of the railway and the towns it serves. It is higher for locations where there are large cities and towns comparatively close together, requiring greater expense on terminal facilities per mile of road than in places like the Western Provinces, where the towns are far apart. But even in some of the small western towns large terminals are being built to take care of the increased traffic induced by the growth of the country.

Items three to seven are ones in which considerable economies can be made if necessitated by the financial status of the company. For example, it has already been stated that money should be expended on first-class terminal facilities, even at the expense of cheaper construction between the terminals. This can be quite satisfactorily done by using more or less temporary construction for some of the smaller bridges and culverts which can be built cheaply, without sacrificing the operating efficiency of the road, and they can easily be replaced by permanent structures when this expense is warranted by the earnings of the road. Similarly in the case of the grading, temporary wooden trestles can be built instead of heavy em-

bankments, but it is not advisable to put in heavier grades in order to save earthwork unless it is absolutely necessary. These trestles can be filled in eventually at a cheaper cost per cubic yard owing to the track being already laid from which the filling can be readily dumped from side dump cars by a rapid unloader. In the case, however, of there being a large cut immediately adjacent to the proposed fill, it is, of course, more economical to use the material from the cut to make the fill when the road is first constructed.

Economies can be made in the tracklaying and ballasting items without seriously effecting the cost of operation, but the maintenance charges will necessarily be higher with light rails and poor ballast. The expense of replacing the light rails and re-ballasting the line will not be disproportionately great.

The other items in the cost of construction are comparatively small percentages and big reductions in them do not make very much reduction in the total cost per mile, but large economies in any of them are apt to cause, indirectly, greater expenses in some of the larger items, or a loss of revenue to the road. That it is a false economy to cut down engineering and legal expenses is becoming more generally recognized among the larger railways. Thousands of dollars may be saved on the construction of a road by having well-organized and equipped engineering staffs working under the guidance of competent men. Similarly economies in station buildings, freight sheds, etc., are apt to adversely affect the revenue of the line.

Annual Traffic—Gross Tonnage.—A comparison of the annual traffic and gross tonnage must be made of the different routes under discussion. The amount of the gross tonnage has to be estimated in a way similar to that already described as the fifth method of estimating probable revenue. The probable gross tonnage must be carefully analyzed so as to obtain figures which will not only apply to the whole route but also to the sections between the intermediate towns. It will be as well to note at this point that it is desirable in estimating gross revenue and gross tonnage to be on the safe side by keeping the figures on the low side in the case of the former and on the high side for the latter. This will prove to give the most satisfactory results in the long run.

Cost of Handling the Traffic.—The features controlling this item are distance, curvature and grades, and we will deal with each of these features in the order named.

Distance.—This is the item on which the rates chargeable for passenger and freight services are based. This is apt to be rather contrary to the value of the service rendered and also to the cost of rendering that service. If the railway adopts a very costly construction in order to reduce the distance betweeen any two points it will be able to give a better and quicker service both for passenger and freight traffic between these points, but, by a strict mileage rate, the actual compensation would be lower than for a longer and cheaper route. On some of the roads in the States serving the large business centres this feature of the increased value of short routes and quick service is illustrated by the fact that an extra charge is made on the fast passenger trains over and above the regular fares between the two points. The actual value of the transportation to a passenger who wishes to go from, say, Montreal to Toronto, is inestimable. If he is travelling purely for pleasure, or for a whim, the money value to him approaches nothing, but if he has to attend to important business the actual value to him of being able to attend to it personally may be many times the cost of his ticket.

The cost of transportation between any two points is only slightly influenced by small changes of distance as it is ruling grades and curvature of the line which most seriously affect this cost, as will be shown later. The effect of change of distance on maintenance of way charges (except in the case where it is a change of a few feet only) is fully proportional to the amount of that change. The expenses of labor and material, etc., will naturally be proportionately increased because it is assumed that in the case of a shorter route there will only be employed sufficient section gangs to properly take care of that line. If the length is increased, either additional gangs will have to be employed or else the existing ones would have to be reinforced.

The cost of bridges, road crossings, culverts and other fixtures of this nature would have to be considered separately for each route, as in some cases the number of bridges, etc., would be identical on the different routes, hence there would be no effect on the cost of structures by a change of distance. With regard to the maintenance of equipment any added train mileage will naturally increase the depreciation of rolling stock and increase the shop expenses, repairs and renewals. The actual mileage run by locomotives, passenger and freight cars is only one of the contributory causes of their deterioration. They deteriorate with age, strains due to stopping and starting, etc. The following table illustrates the effect of large and small change of distance on operating expenses:

TABLE VI.

	Normal average.	Cost per mile p.c. large.	small.
Maintenance of way and structures	20.09	18.11	15.53
Maintenance of equipment	22.74	9.18	8.50
Traffic expenses	3.08	0.00	0.00
Conducting transportation	50.54	21.69	9.21
General expenses	3.65	0.00	0.00
	100.00	48.98	33.24

In the above calculations it has been assumed that the business done by the road is fixed and invariable and would be unaffected by any changes in the length of the line. A change of length in order to reach a possible source of traffic would naturally affect the tonnage and consequently the number of trains required to handle it, but the rest of the line might be so burdened by an excess haul that the traffic might be discouraged. A saving in time between two points by a reduction of distance is—except in a very few cases—not to be effected except by a great expenditure which can hardly be justified by the time saved. The reduction in distance will have no effect on the freight business so far as the small saving in time is concerned, and may tend to reduce the rate considerably between the two points under discussion. The effect on the passenger traffic (except in the case of competing lines between large business centres) is comparatively small and the speed of trains is controlled to a large degree by the curvature and grades of the line.

Curvature.—Curvature increases the resistance to traction and, when uncompensated on grades, may be said to increase the rate of grade. When a curve is located on the ruling grade it has a controlling effect on the length of trains. Insofar as passenger traffic is concerned, curvature has very little effect beyond limiting the

speed of trains when the sharpness of the curves is over a certain amount varying with different conditions. On competing lines, however, this may be a serious matter, not only on account of time lost, but also due to the apprehension of danger, and because the curvature may produce rough and unpleasant riding. These objections to curvature may be almost entirely eliminated as regards the number of trains required to handle the traffic as the only feature which might control this is the possible increase of a ruling grade by an uncompensated curve, and this may readily be eliminated by compensating curves on ruling grades. On minor grades uncompensated curvature has but little effect, as it merely increases the rate of grade, and unless the original grade plus the increase in grade due to curvature does not exceed the ruling grade it will not limit the tonnage of trains in any way. If, however, the combined effect would be to make the resistance more than that due to ruling grades, then trains loaded up to the maximum for those grades would be liable to stall on the curve.

Grades on the lower side of a stopping place need not be compensated for curvature, because the resistance due to the curve will reduce the work required in braking the trains. When a curve occurs above a stopping place it should be compensated in an even greater degree than ordinarily.

Curves should evidently be compensated an amount equal to that grade which would produce the same resistance as the curve. The resistance due to curvature being a variable quantity depending on the speed of trains, compensation for fast passenger trains may be made quite low, but for slow and heavy freight trains, which are the most important, it must be gradually increased. Webb advises 0.04% to 0.05% per degree for ordinary degrees of curvature. The maximum degree of curvature permissible on any road is a matter on which opinions differ considerably. Some roads limit their engineers to a maximum curvature of 6 degrees, others leave this to the judgment of the engineer. There is no serious objection up to a certain limit to a few sharp curves where the amount saved may be sufficient to justify their introduction. One limiting feature of the maximum curvature is the ruling grade. For instance, where the ruling grade on a line is 0.4% and the rate of compensation has been fixed at 0.4% per degree of curve, it is obvious that a ten-degree curve is the maximum permissible, as this degree has theoretically the same resistance as a .4% grade, and if the 10-degree curve was located on a ruling grade to be correctly compensated the grade would have to be eliminated entirely.

Curvature has a very marked effect on the maintenance and operating expenses of a line. Rails on curves wear much more rapidly than those on tangents; it has been computed that the wear on a rail on a 10-degree curve is 226% of the rail wear on a tangent, under similar conditions of traffic, and that it is approximately proportional to the degree of curve. Ties are also adversely affected by curvature owing to increased rail cutting, and they need more frequent respiking. Wellington states that the deterioration of ties is also proportional to the degree of curve. That part of the roadbed under sharp curves has to be more frequently reballasted, especially when the superelevation is high. The expense of repairs and renewals becomes greater owing to the harder wear on locomotive tires and wheels, thus increasing shop expenses.

The increase of tractive resistance due to curvature naturally tends to increase the fuel consumption of locomotives. Webb charges 44 of the average cost per train mile for an addition of 528 degrees of central angle into a mile of track. In some mountainous regions where a number of sharp curves are unavoidable operating expenses may be sometimes increased by locating these curves in deep cuts, thus necessitating the use of watchmen to warn trains of obstructions due to snow slides, etc., or, as an alternative, the speed of trains must be reduced as they pass these places.

The following table (abbreviated from Webb) gives some idea of the items affected by curvature, being based on the addition of 528 degrees of central angle into a mile of track.

TABLE VII.

Item.	Normal average.	Cost per mile per cent.
Maintenance of way	20.09	5.93
Maintenance of equipment	22.74	28.70
Traffic expenses	3.08	0.00
Conducting transportation	50.44	5.02
General expenses	3.65	0.00
	100.00	39.65

It will be seen from this table that an addition of 528 degrees of central angle into a mile of track increases the expenses per train mile by 39.65% of the average cost per train mile. Assuming that the increased expense is directly proportional to the amount of curvature, which, in the majority of cases, is very nearly true, then one degree of additional central angle per mile would increase the train expenses by .075%. If, again, we assume that the average cost per train mile to be $1, the cost per annum per daily train would be 27.375c. This result is, of course, entirely approximate but will give a better idea of the value of a proposed change than any unbased estimate, and will show whether the improvement will be justified, due to possible increase in business.

Grades.—The effect of grades on train expenses is of the greatest importance. Tonnage of trains is fixed by the ruling grade on the section of line under consideration, a heavy ruling grade necessitates shorter trains and consequently more of them. Gross receipts from traffic is a fixed quantity regardless of the number of trains necessary to handle it, while the cost of handling the traffic will be nearly proportional to the number of trains. A reduction of ruling grade, on the other hand, reducing as it does the number of trains and therefore the operating expenses, will justify a large expenditure to accomplish this result. Where the line runs through comparatively level stretches of country with light grades, very little can be done to favorably affect the grade, but humps and sags in otherwise uniform grades may be eliminated. No figures on the resistance to movement of a train on straight level track can be considered accurate for all cases, as they depend on speed, length of trains, character of cars, and condition of weather and roadbed, but 10 lb. per ton is frequently taken for average conditions and velocities. This is equivalent to the retarding effect of a 0.5% grade.

The rate of ruling grades are necessarily limited by the general character of the road. A road designed to meet the requirements of light traffic would naturally not be justified in a large expenditure to reduce the rate of ruling grade, whereas on a road built for heavy traffic this would be of prime importance. Methods of operating the trains will, to a large extent, minimize the effect of ruling grades, the road being divided into divisions, at the termini of which sorting yards may be located, and the trains

increased or decreased when the grades on the next division make this advisable. If the road has necessarily to pass over a summit between two points and the natural grade is very high it may be advisable to use pusher engines on this high grade, a lower rate can then be used for the ruling grade.

On most roads the ruling grades affect only the heavier class of freight trains, the lighter freight and passenger trains being usually well under the maximum tonnage capacity of their locomotives. The cost of operating is dependent on the number of trains and not on their tonnage, and an extra train means an extra locomotive, train crew, etc., and this extra engine and train will also increase the maintenance of way charges due to the additional wear and tear of the track.

A small saving is made by having fewer cars per train due to the lighter work on the engines, when hauling over the minor grades and level sections. The following table gives an idea of the effect on different items of operating (n + 1) trains on heavy ruling grades compared with the cost of operating "n" trains on light grades, the tonnage being the same in both cases:

TABLE VIII.

Item.	Normal average.	Cost per mile per cent.
Maintenance of way	20.09	7.45
Maintenance of equipment	22.74	5.88
Traffic expenses	3.08	0.00
Transportation	50.44	28.30
General expenses	3.65	0.00
	100.00	41.63

In estimating the probable train mileage of a new road the estimated tonnage, ruling grades and the type of engine to be used must all be taken into account. It is possible to get an approximation of the hauling capacity of any type of locomotive over the ruling grades. In practice the engine is not loaded up to capacity, the reduction being dependent upon the rate of grade and its length. In general, this reduction will be as follows:

Grades of 0.3% to 0.6%, reduction 25% to 16%
Grades of 0.7% to 1.0%, reduction 14% to 10%

Dividing the estimated tonnage by the hauling capacity of the engine and multiplying by the length of the line will give the train mileage. Multiplying this by the cost per train mile will give the yearly cost of operating. The saving resulting from adopting a lower ruling grade or using pusher engines in isolated cases of heavy grades may thus be determined.

The last of the 92 leaves for the miter gates of the Panama Canal locks was lowered into place on its hinge pintle on Thursday, October 30th. This was the side wall leaf of the lower operating gate in the east flight at Miraflores Locks. The lower operating gates at Miraflores are the largest in the Canal construction, each of the lower leaves being 82 feet high and weighing over 700 tons. The swinging of a leaf means the completion of its erection, sheathing, and most of the riveting and reaming, but it is a step toward final adjustment. The work of lining up and babbiting the nickel steel bearing plates at both ends of a leaf can be completed only after the leaf is swinging in operating position, and the leaves are yet to be tested, painted inside and out, and fitted with foot-walk and handrail.

ELECTRIC LOCOMOTIVES FOR MOUNT ROYAL TUNNEL.

VARIOUS features of the tunnelling of Mount Royal, by the Canadian Northern Railway, in order to reach a terminal in the centre of the city of Montreal, have been described in *The Canadian Engineer* during the past year. Attention is directed to Jan. 16th issue, outlining the essential engineering aspects of the scheme; to Feb. 6th issue for an article descriptive of the early operations and the plant equipment; to Feb. 27th issue dealing with the precise survey work in connection with its location, and to the issue of June 12th, where mention was made of the remarkable speed with which operations were progressing. In Oct. 9th issue the announcement was made of the contract for the electrification of the tunnel having been let, as, in the design, considerations of cleanliness and health pointed to the use of electricity as the motive power. The present article contains a few points of interest with respect to the design of the locomotives selected.

The equipment for the electrification of the tunnel and terminals, for which the Canadian General Electric Company, Limited, has the contract, includes 6 electric locomotives designed for an operating potential of 2,400 volts with overhead trolley construction. Two of these locomotives, operated and controlled as a single unit, will have ample capacity and suitable speed requirements for handling the heavy transcontinental passenger trains—1,130 tons trailing load—within the Montreal terminal zone. A single locomotive will successfully handle the freight trains—1,000 tons trailing load—and the local passenger service—500 tons trailing load.

Locomotives.—The general type of the locomotive proposed is that known as the box cab, articulated running gear type of locomotive. Its estimated weight is 83.0 tons. The locomotive has four axles with all of the weight upon the eight driving wheels, thus securing the maximum adhesive weight on drivers. The running gear consists of two 4-wheel trucks, articulated together by a heavy hinge. The equalization of the trucks is accomplished by a heavy locomotive type semi-elliptic leaf spring over each journal box, connected through spring hangers to the frame and to the equalizer bars. Practically a 3-point suspension is thus supplied through the side equalization of one of the trucks and both side and cross equalization of the other truck. With the Miner friction draft gear mounted in the end frame casting of the truck, this type of construction restricts the hauling and buffing stresses of the truck side frames and articulated joint, instead of through the cab centre plate. This relieves the cab and apparatus from the effect of severe shocks.

Both the box cab and platform are built of plates, sheets, angles and heavy channels, and are thoroughly reinforced throughout. The box cab is divided into three compartments: the apparatus compartment in the centre and the two operators' compartments at the ends. Each operator's compartment has a full complement of apparatus, consisting of controller, control switches, meter, air brake control apparatus, air gauges, pantagraph control and heaters, thus providing the locomotive with a complete double-end control. All apparatus subject to 2,400-volt potential is located in the centre apparatus compartment and properly screened to protect against accidental contact. The location and general arrange-

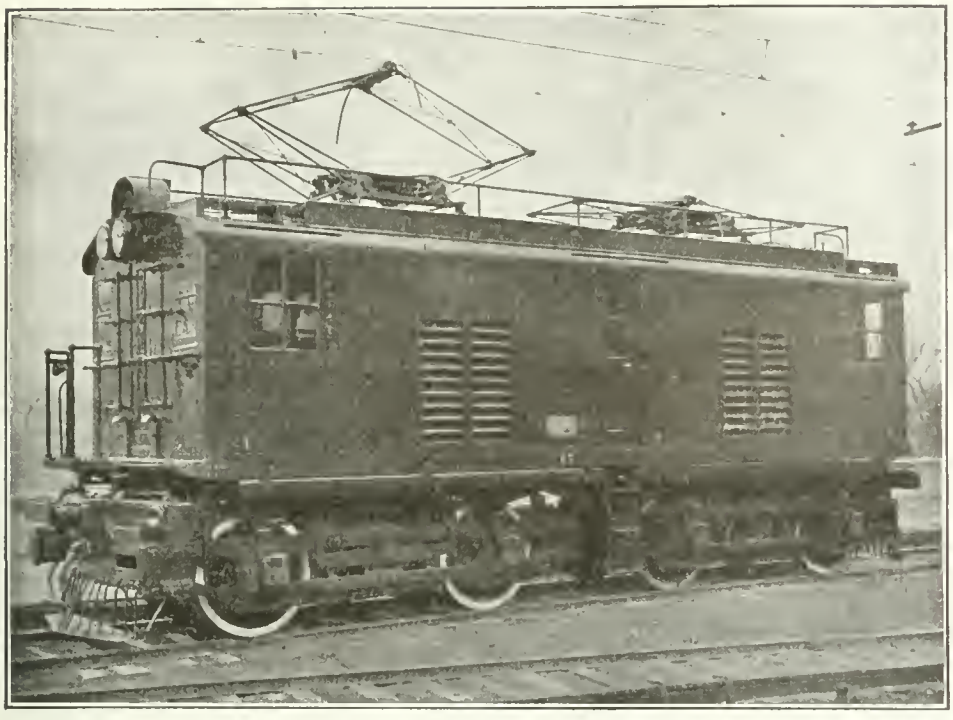

Fig. 1.

ment of this apparatus is such as to provide easy access from all sides for inspection, cleaning and repairs.

Control Equipment.—The Sprague-General Electric Type "M" multiple unit double-end control equipment is proposed for the locomotives, all the control points being proportioned and adjusted so as to secure a smooth and even acceleration, at all times, corresponding to a current consumption near the slipping point of the wheels. The transition between series and series-parallel is effected by a special electro-pneumatically operated change-over switch and the motor fields will always be on the ground side of the armature.

A motor generator set will supply 125-volt energy for the operation of the control and a 2,400-volt air compressor of 100 cubic feet free air piston displacement is provided as part of the air brake equipment. Two air-operated roller pantagraphs and a properly insulated bus line are located upon the roof. The bus line will supply power to two or more units from the pantagraphs of any of these units.

The motor equipment consists of four C.G.E. -229 commutating pole type motors wound for 1,200 volts and insulated for 2,400 volts, so that two may be connected permanently in series and operated on a 2,400-volt circuit. These motors are geared to the wheels through twin gears, there being one pinion on each end of the armature shafts. The C.G.E.-229 motor is especially designed for locomotive service and is provided with forced ventilation by a blower located in the apparatus compartment. The locomotives are geared for a free running speed on tangent, level track of approximately 45 miles per hour and will be operated as two-speed machines with ten points in series and nine points series-parallel.

The air brake equipment will be the straight air and automatic type so as to combine the desirable features for train operation through an equalizing reservoir and the independent operation of the brakes upon the locomotive. Provision is made for the multiple operation of the compressors upon all locomotives when operating in multiple so as to distribute the duty upon all the compressors in the train.

Operation of Motors.—The motors will be operated by the Sprague-General Electric Type "M" two-speed control arranged to operate the motors in series and series-parallel. The external regulating resistance is divided into two parts, each part being directly connected to a pair of motors permanently connected in series. The two pairs of motors, with their resistances, are all connected in series on the first point of the control, the resistance being varied through the first nine points on the controller and finally short circuited on the tenth, or running point. The two pairs of motors are then similarly operated in series-parallel and all resistances cut out on the last or full speed running point.

A special electro-pneumatically operated change-over switch is used to make the transition between series and series-parallel so that there will be no appreciable

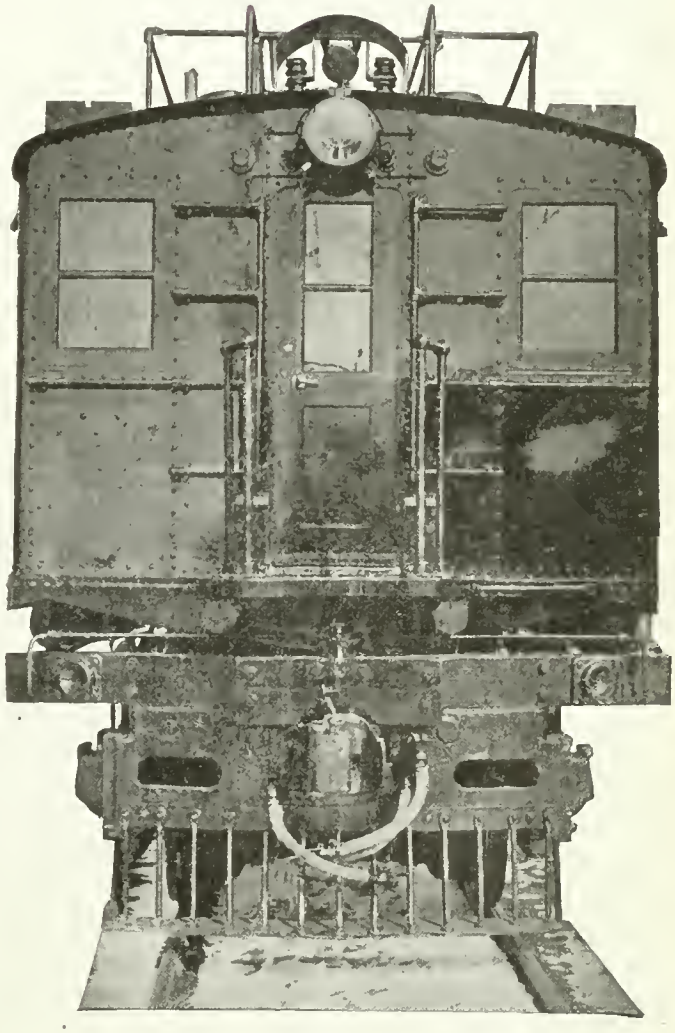

Fig. 2.

reduction in tractive effort during the change. A smooth transition between all points, both rheostatic and transitional, insures motor operation close to the slipping point of the wheels and a steady, gradual acceleration at all times.

The motors have sufficient capacity to slip the wheels, the slipping point serving as a current limit to prevent overloading. Either pair of motors may be cut out, in case of emergency, by means of a special handle on the change-over switch.

Controllers.—The master controllers receive their energizing current at a potential of 125 volts from the motor generator set and provide for operating the contactors so that they close the motor circuits under different combinations and regulate the external motor resistances to give 10 points series and 9 points parallel. The controller is of the non-automatic type and has two handles: one regulating the applied voltage at the motors and the other for controlling the direction of rotation of the motors. Each of the above handles control a single cylinder.

Pantograph Trolleys.—The overhead trolleys are of the pantograph type, mounted on insulated bases and pneumatically operated. A hand pump is provided for raising the trolley in case a locomotive has been standing some time and has no air supply.

Automatic Stops.—Provision is made for automatically opening the control circuit and cutting off all power from the locomotive, in case the engineer over-runs a signal set against him. At the same time a special valve is opened which will set the emergency air brake.

The huge scheme, undertaken at a cost of £3,500,000 sterling, of the provision of a water supply for the gold fields of Western Australia, is a wonderful piece of hydraulic engineering work, and is now well advanced. The primary purpose of the work was not to insure the subsistence of a large community of people, but to maintain and develop a staple industry established in a practically waterless district 400 miles from the western coast of the state. A daily supply of 5,600,000 gallons was to be provided, of which 5,000,000 were for use in the gold fields. The source of supply is an artificial reservoir, from which the water is pumped through a steel conduit 80 inches in diameter by means of eight pumping installations to the main distributing reservoir at Bulla Bulling. This reservoir is 308 miles from the main reservoir and is 1,200 feet above the lowest outlet level of the latter. The water then gravitates a distance of 44½ miles to the Coolgardie service reservoir and the Kalgoorlie service reservoir. The details of all the ironwork used in the construction of the weir were drawn out in the state and all the ironwork used was obtained from Great Britain, and it says much for the accuracy displayed in the drawings that on being grouped together as the work progressed all parts fitted correctly into their proper places. An interesting feature of the work at Kalgoorlie was the use of camels for excavation purposes. According to figures supplied for the use of the Christian Science Monitor by Neil McQueen, the district engineer, 86 camels were used for the excavation work, which was in stiff clay, in connection with the Kalgoorlie reservoir. This reservoir will be lined with a bitumen asphalt compound invented by P. V. O'Brien, the chief engineer in charge, and will be roofed with corrugated iron to keep dust out of the water and prevent evaporation. The reservoir, which is circular, has a diameter of 378 feet and a depth of 22 feet at the deepest part. Its capacity is 10,000,000 gallons.

THE CORROSION OF PIPES BY RAW AND TREATED WATERS.

THE lengthy series of investigations based upon the corrosion of iron pipes by water supply was carried on during 1912 by the Department of Water Supply, Gas and Electricity of New York City. The results of these experiments are contained in a paper read recently before the American Public Health Association by Mr. Frank E. Hale, from whose paper the following information is deduced:—

The presence of carbonic acid is the most potent factor in connection with the presence of dissolved oxygen. The action of these two agents is modified by the presence of other salts, increased by nitrates which furnish oxygen by reduction, and decreased by carbonates which help to form protective coatings upon the pipe. The chemical action takes place in the following order:

The first reaction is the solution of iron as bicarbonate by carbonic acid with the formation of hydrogen. The dissolved oxygen in the water which is near the iron surface oxidizes some of the hydrogen back to water. After the oxygen near the iron is used up the hydrogen remains as a gas. In the cold reaction of the experiments the amount of hydrogen oxidized was found to be about 20 per cent. The dissolved oxygen at the same time oxidizes the soluble iron bicarbonate to insoluble red iron, setting free again the carbonic acid. The carbonic acid set free again dissolves more iron, and is again set free, until all of the dissolved oxygen is exhausted. The red iron oxide then acts as oxidizer until it is completely reduced to black magnetic iron oxide, setting free carbonic acid again. Reduction does not take place beyond this stage. After all dissolved oxygen has been used up nitrates are completely reduced to ammonia, serving to supply oxygen. After all possible sources of oxygen are exhausted the carbonic acid disolves more iron, which is probably thrown out of solution finally as insoluble basic carbonate of iron, since after complete reaction there is only about 0.2 to 0.7 p.p.m. iron in solution, no free carbonic acid, no dissolved oxygen, no nitrate, sometimes no bicarbonic acid, and under some conditions caustic lime is present. The alkalinity of hard waters is reduced to about 25 p.p.m.

The carbonic acid for the solvent action may be derived from three sources—the free carbonic acid, the bicarbonic acid, and the neutral carbonate. In the latter case the carbonate hydrolyzes so that there are in solution neutral carbonate, lime hydrate and carbonic acid. This takes place when the water reaches the stage that only neutral carbonate is present. The carbonic acid set free dissolves the iron. The presence of lime hydrate was proven by titration with phenolphtalein and methyl orange.

The rapidity of corrosive action is affected by the source of carbonic acid in order as given above, and the amount of soluble iron present during the active stages of corrosion varies with the above order of source of carbonic acid.

Another source of carbonic acid is that set free in alum-treated waters. This is really mostly bicarbonic acid set free. The amount set free per grain of alum per gallon is not, as sometimes stated, 6.8 p.p.m., but about 3.5 p.p.m. (determined by analysis).

It must be understood that the facts as given above apply to new pipe with a clean iron surface and to complete reaction.

Attempts to remove dissolved oxygen from water appear to me to be hopeless as well as expensive, because a consideration of the above reaction brings out a fact that

seems to me to have escaped general attention, and that is that 15 per cent. of the oxygen in the iron oxides formed by complete reaction, if all the hydrogen were set free, comes from the water and not from the dissolved oxygen, and the greater part of the hydrogen is set free.

A very large amount of iron is corroded for each part per million of dissolved oxygen through the catalytic action of carbonic acid and water. For example, 10 p.p.m. of dissolved oxygen produces 126 p.p.m. Fe_3O_4 expressed as Fe, whereas if the hydrogen were oxidized and not set free the amount which 10 p.p.m. oxygen could produce would be only 31 p.p.m. iron. In our experiments 75 to 80 per cent. of this theoretical amount of iron was produced, the difference from theory being due to oxidation of hydrogen. This is a variable quantity, but about 85 per cent. of the hydrogen oxidized was oxidized during the first 15 minutes, which substantiates the idea expressed previously that oxidation of hydrogen takes place only at the surface of the iron while dissolved oxygen is present near the iron. The presence of hydrogen gas is easily shown and has been proven by many investigators. Any hydrogen set free means an equivalent amount of oxygen obtained from the water to oxidize the iron.

Experiments Conducted With Three Kinds of Pipe.—The experiments were carried out with Byers wrought iron pipe (protected with an inside coat), Reading wrought iron pipe, lack mild steel, and galvanized wrought iron. The first three showed no difference in the corrosive action when carried to completion, but the steel appeared to corrode most rapidly. The galvanized iron showed great resistance at first, but gradually—especially with alkaline water—the action increased somewhat, though in the time of our experiments the highest amount was only about one-third that of the other pipes.

Experiments with regard to speed of reaction brought out some surprising facts.

About 50 per cent. of the iron produced by corrosion in the cold is produced in two to three hours.

With Croton water (5 p.p.m. free carbonic acid) the action is practically complete in 15 hours. This explains the greater tendency in house service—especially in new services—to show rusty water when first drawn in the morning, since the action is complete over night.

The rate of corrosion is increased proportionately to the increase in free carbonic acid. The action cold was complete in seven to eight hours with Croton water containing 25 to 50 p.p.m. free carbonic acid. The total iron was also somewhat increased with the higher free carbonic acid. The carbonic acid hastens the action by dissolving the iron more rapidly. There being more iron in solution, oxidation is hastened. Analyses for soluble iron and dissolved oxygen proved this to be true. The carbonic acid increases the total iron by forming basic carbonate of iron which is left unoxidized after available oxygen is exhausted.

Alum-treated water showed no appreciably greater corrosive action either in speed or total amount of iron than untreated water. This is due to the comparatively slight increase in free carbonic acid (3.5 p.p.m. per grain of alum per gallon).

Neutralization of the free carbonic acid retards the corrosive action. Neutralization of the free carbonic acid by lime hydrate or by sodium carbonate retards the corrosive action. Neutralization of the free and half-bound carbonic acid by lime hydrate, provided there is no excess caustic, still further retards the corrosive action, and also reduces the total iron produced by cold action 33 per cent., and by hot action 50 per cent. Neutralization of carbonic acid retards corrosion by reducing the amount of dissolving agent, hence the amount of soluble iron present at any moment, and thus slows up the oxidation.

The slightest excess caustic (a few p.p.m.) up to considerable excess hastens corrosion to almost indentically the same degree as does increasing the free carbonic acid to 25 to 50 p.p.m. A large excess of soda-ash acts likewise. The action of alkalis has been noted by Cushman and others.

Excess alkali hastens the corrosion by hastening the absorption of oxygen by the iron in solution, though this is smaller in amount at any time. Until the excess of alkali is sufficient to prevent hydrolysis of carbonates the corrosion takes place. Analyses proved that the oxygen is absorbed faster and that only traces of iron are in solution at any time. Compare in this connection the Levy method of determining dissolved oxygen in water—i.e., oxidation of ferrous salts in alkaline condition.

Red Water Trouble Caused by an Excess of Iron Dissolved or Suspended.—The excess of alkali necessary to stop corrosion completely is 100 to 125 p.p.m. excess lime hydrate over that needed to neutralize the free and half-bound carbonic acid. Only slightly more is needed to stop corrosion hot than cold. This amount of excess alkali acts by completely preventing solution of iron, for the oxygen still oxidizes the surface of the iron and is completely gone in twenty-four hours, although no iron over the original amount appears in the water.

The above facts show that whatever helps to put iron into solution is the real cause of red water trouble. It is the iron in the water, dissolved or suspended, which causes trouble—not the iron clinging to the pipe.

All corrosive action was hastened by heat (120-150° F.), so that complete reaction was accomplished in one and a half to three hours on the clean iron surface. Heat hastens corrosion in at least four ways—by hastening the chemical action of solution of iron, by increasing the amount of free carbonic acid since heat sets free the half-bound carbonic acid of the alkalinity, by creating convection currents that cause the dissolved iron to diffuse more rapidly and hence come in contact with the dissolved oxygen faster, and by hastening the oxidation and precipitation chemically of the dissolved iron.

The water of the Flatbush Water Company, which has a hardness of about 140 p.p.m., contains only two-thirds as much oxygen as Croton water and 10 p.p.m. free carbonic acid, produced corrosion as rapidly as Croton water on the clean iron surface and a total amount proportional to the oxygen and carbonic acid content as required by theory. Yet in service this water causes no complaint and is generally free from iron and turbidity. This is undoubtedly due to protective scale formed on the pipe, probably consisting of both iron oxide and carbonate of lime. As previously stated, the alkalinity of hard waters is reduced to about 25 p.p.m., when the action goes to completion.

Dissolved oxygen disappears rapidly in all cases. In the first fifteen minutes 23 to 37 per cent. were used up due to oxidation of both hydrogen and dissoved iron.

The relative speed of oxidation is best seen in comparing percentages of oxygen used up to one and a half hours.

So long as there is oxygen in solution the reaction takes place rapidly and almost proportional to time and the iron precipitate is red (Fe_2O_3). After exhaustion of the oxygen the reaction becomes slower, the red oxide being reduced to the lower black oxide, turning green to

brown to black. The color of the precipitate gives a good indication of the progress of the action.

While there is dissolved oxygen present there is iron in solution, depending upon the amount of active carbonic acid. Soon after the oxygen disappeared it was but rarely that more than 0.5 to 1.0 p.p.m. iron was in solution. It is obvious that the amount of dissolved iron is greater with increase in the active carbonic acid.

The amount of oxygen within wide limits does not seem to affect the rate of corrosion materially, but the total amount of iron removed from the pipes in complete reaction, other factors remaining the same, is directly proportional to the dissolved oxygen in the water.

When iron pipe is exposed to the continuous action of water, as in service, a protective coating forms according to the nature of the water. Its action is to delay corrosion rather than to stop it, and to reduce the amount of iron appearing in the water. The corrosion goes on slowly, but the oxides cling to the iron, increasing the amount of scale. In cold action the greatest protection was acquired experimentally in ten days, and then remained constant. Flatbush and Brooklyn waters caused a better protective coating than Croton water. The iron produced in 24 hours dropped from 114 and 84 p.p.m. respectively for the two former to 21 p.p.m., Fe, for the Croton, and its modifications from 56-102 to 29-35 p.p.m., Fe. Croton was tried in four modifications—untreated; with free carbonic acid neutralized by sodium carbonic acid; neutralized by lime hydrate to bicarbonate, and treated with one grain of alum per gallon.

In hot action the protective coating formed in two days. Flatbush water reached the lowest level of 3 p.p.m. iron with an average of 8. Brooklyn water reached 4 p.p.m. iron with an average of 9. Untreated Croton fluctuated high and low with an average of 41 p.p.m. iron. The alum-treated Croton averaged 26. The soda-neutralized Croton averaged 23 p.p.m., Fe. All the averages, cold and hot, include results from the tenth to the twenty-first day.

The pipes which had acquired a protective coating from these different waters were subjected for 24 hours to the action of untreated Croton water and to Croton water containing 20-27 p.p.m. free carbonic acid. The water with increased carbonic acid produced an average of 38 p.p.m. iron from the pipes with scale formed in cold action, against 24 p.p.m. produced by untreated Croton (5 p.p.m. CO_2). On the pipes with scale produced in hot action about the same relative quantities were produced, 34 against 22 p.p.m., Fe, showing that water containing the greater amount of carbonic acid causes more corrosion upon pipes protected by scale.

The scale produced by Flatbush, Brooklyn and soda-neutralized Croton water proved the more protective.

General Summary.—Extensive corrosion takes place rapidly in new pipe while the iron is fairly clean from incrustation. This explains the abundance of complaints of iron rust in new service installation.

Concerning the kind of pipe, there is little doubt that steel pipe is most readily attached, wrought iron next, and galvanized iron the least. The latter is far preferable for use. Lead pipe should never be used any more than absolutely necessary because of the danger of accumulative poisoning with minute amounts of lead (less than 0.5 p.p.m.).

The chief agent in dissolving the iron is carbonic acid, as it is also the chief agent in holding iron in solution.

The chief agent in carrying the rusting to the greatest extent is oxygen.

Through the catalytic action of active carbonic acid about 70 per cent. of the oxygen in the iron rust comes from the water by chemical decomposition, hydrogen gas being set free. The remainder only, about 30 per cent., is furnished by the dissolved oxygen in the water.

Soft Water Containing Much Free Carbonic Acid Causes the Most Trouble.—Waters which give the most trouble are very soft and contain considerable free carbonic acid.

Hard waters rarely cause complaint, as they form an excellent protective coating on the pipes.

The action in distribution services probably never reaches completion on account of protecting scale of oxide, etc., which retards corrosive action. The scale varies with different waters in protective properties. Tap samples in New York City have shown no appreciable diminution in dissolved oxygen or in free carbonic acid, so that only slight corrosion can have taken place in proportion to volume of water and possible reaction. Even hot services have shown the usual amount of carbonic acid and more oxygen than would saturate the water at the temperature when drawn.

Since in distribution services there is no exhaustion of oxygen, any increase in free carbonic acid may mean a possible increase of soluble iron in the water, which would be precipitated in the hot water supply.

Neutralization of free and half-bound carbonic acid is impracticable as it tends to hasten corrosion if there be the slightest excess of hydrate, removes zinc when hot from galvanized pipe, interferes with alum precipitation and color removal, and produces considerable precipitation of calcium carbonate in the water, which would deposit in the pipe system, meters, etc., unless previously removed by filtration or sedimentation.

Neutralization of only free carbonic acid is feasible, since it retards corrosion and reduces the amount of soluble iron.

Either soda-ash or lime oxide may be used. Both reduce the corrosive action, cold or hot. Only sufficient lime should be used to form bicarbonate. This reagent increases the hardness 1.1 p.p.m. for every 1 p.p.m. free carbonic acid neutralized to bicarbonate. About 5.3 lbs. CaO per 1,000,000 gals. of water are required for each 1 p.p.m. carbonic acid. It is best handled dry. It costs about 2 cents per 1,000,000 gals. per 1 p.p.m. carbonic acid.

Soda-ash is more soluble, can be handled in concentrated solution and consequently in small-sized tanks, and probably with better regulation of dosage would not increase the hardness, but, on the contrary, would decrease the lime sulphate in the water, changing it to sodium sulphate, thus improving the water for boiler use and for other industrial purposes. It also apparently helps to form a better protective coating on the pipe. About 20.2 lbs. soda-ash per 1,000,000 gals. of water are required for each 1 p.p.m. carbonic acid. This would cost about 20 cents per 1,000,000 gals. for each 1 p.p.m. carbonic acid. Soda-ash has been used successfully on a small scale to obviate red water trouble. The great difference in cost is due to the greater molecular weight, less combining power and greater cost per pound. The cost must be considered in connection with the degree and advantage of the change of sulphates to carbonates, etc.

Aeration of water by splashing followed by neutralization of residual free carbonic acid (about 5 p.p.m.) is probably the best practice.

FIXED CARBON DEPENDS ON CRUDE

CHICAGO EXPERT SAYS THAT HIGH FIXED CARBON IN REFINED ASPHALT IS NOT AN INDICATION OF CRACKED OIL IF CRUDE ALSO HAS HIGH FIXED CARBON

By LESTER KIRSCHBRAUN, B. S.,
Director Chicago Paving Laboratory.

(NOTE.—*Mr. Law, in our issue of November 20th, and Col. Howard, issue November 27th, favored the elimination of the Fixed Carbon Test. Mr. Pullar advanced an original suggestion in our issue of November 13th—that the Fixed Carbon Test be retained in specifications but that all asphalts be classified according to their sources and a different maximum limit be imposed for each class. In the following article Mr. Kirschbraun agrees with Mr. Pullar that the test has certain usefulness, and urges consideration of the liquid crude when imposing a maximum limit for fixed carbon in the refined product. He gives a formula establishing the permissible fixed carbon in any asphalt refined from crude of known fixed carbon, but it is of the empirical class of formulae against which Mr. Law presented strong arguments in his article. This shows the difference of opinion among engineers and chemists on this test.* THE CANADIAN ENGINEER *would like to hear from municipal highway or consulting engineers or road contractors who may have definite opinions regarding the Fixed Carbon Test.*—EDITOR.)

SINCE Mexican asphalt has come upon the market, there has arisen considerable comment upon the value of fixed carbon tests. Mexican asphalt has generally shown a high fixed carbon figure, and in many cases it fails to meet specification requirements where the usual maximum is given. On this account, rather than upon the merits of the matter, various producers have advised the elimination of this requirement in specifications. While the arguments presented in this direction are rather of a commercial origin, there is no question but that there should at least be a revision of this clause if retained in asphalt specifications.

In the following discussion the writer shows that the fixed carbon figure in asphalts produced from liquid crude is dependent, among other conditions, upon the nature of the crude from which such asphalt is obtained. It will be observed that the hydrocarbons yielding fixed carbon are, in the course of distillation, retained in the asphaltic product. This product will then have a normal fixed carbon figure represented by the quotient of the fixed carbon in the crude, divided by the percentage yield of asphalt. This applies under theoretically ideal refining conditions.

For example, if we have a crude showing 8% of fixed carbon and the yield of asphalt obtained therefrom is 50%, we should normally have a product giving 10% of fixed carbon. On the other hand, if we have a crude showing 4% of fixed carbon, the product should normally give 8%, on the basis of 50% yield.

If, however, refining conditions are not perfect, there will be formed decomposition products, the hydrocarbons of which yield fixed carbons, and thereby give to the resulting product an increased fixed carbon figure over and above that derived from the normal content of the crude. This is a matter of fact observation. The fixed carbon figure, thereby becomes an index of this decomposition, and herein lies the significance of the test as also the danger of its application.

It is evident that the results must be properly interpreted in the light of the above conditions, and this is only possible when the character of the crude is known, and also the yield of asphalt obtained therefrom. This is a simple matter when applied to refinery control or to inspection work at refineries, but presents some difficulties when applied in specifications generally. It is thought, however, that to those having a sufficiently wide knowledge of crude materials and methods employed in production, this would prove no special difficulty, even though it should be necessary to make tests of crudes and laboratory products in order to determine proper standards.

In the light of the present knowledge of the subject, the writer has arrived at the following tentative conclusions regarding the value of the fixed carbon test:—

(1) As a matter of refinery control it is extremely valuable in gauging the efficiency of the distilling operation.

(2) To the asphalt chemist familiar with crudes and methods of obtaining asphalt therefrom, it is a valuable indication of the care used in refining.

(3) If the fixed carbon requirement is embodied in specifications no fixed maximum should be stated unless such limit takes into consideration the effect of the character of the crude material. In order, therefore, to properly incorporate a fixed carbon requirement in specifications, the writer would suggest a clause (this referring to material of approximately 50 penetration) somewhat as follows:—

"The yield of fixed carbon obtained upon ignition of the asphalt cement must not exceed 14%, unless the amount is smaller than 3% in excess of the quotient of the fixed carbon from the crude, divided by percentage yield of asphalt."

To state this mathematically and to better advantage, the fixed carbon in the asphalt cement should not exceed

$$\frac{\text{Fixed carbon from crude}}{\text{Per cent. yield asphalt}} + 3\%$$

In other words, where the test shows in excess of 14% of fixed carbon, the above formula will apply if such excess is due to the character of the crude from which the asphalt is produced.

So far as known to the writer, the fixed carbon test was first generally applied to the bitumens of the paving industry by Mr. Clifford Richardson. Following, fixed carbon requirements have been largely introduced in specifications for paving asphalts and road binders. The value of this test has been subjected to considerable question, and in many instances much confusion has arisen through improper and empirical interpretation of results. Fixed carbon determinations must be properly considered in connection with other analytical data and further, in

connection with the character of the bitumens under examination. When so considered, the writer is of the opinion that the fixed carbon test has a decided value in specifications and is capable of yielding much information to the experienced asphalt analyst.

The writer explained in detail his understanding of the significance of fixed carbon determination in a paper before the American Society for the Advancement of Science, and presented the following laboratory data and explanations thereof, upon which his conclusions have been based.

Fortunately, the method of determining fixed carbon is fairly well standardized, and unlike many other methods employed in the examination of asphalts, the procedure at least is uniform. The method used is that recommended by the committee on coal analysis of the American Chemical Society, published in Vol. 21 (1899) page 1116. Briefly, it may be described as follows: A sample of one gram of the bitumen to be examined is weighed into a previously tarred platinum crucible of about 30 c.c. capacity, provided with a close-fitting cover. This is ignited for exactly seven minutes on a platinum triangle over a bunsen burner carefully regulated so as to give a flame 6-8 cm. high to the top of inner cone and fully 20 cm. high to the tip. The platinum crucible is placed ½ cm. above the tip of the inner cone. The ignition should be carried out in a place free from draft and permitting a steady flame. At the end of 7 minutes the crucible is removed from the flame, cooled in a desiccator and weighed. It is then returned to the flame, uncovered, turned on its side to give access to air, and ignited until all carbonaceous matter is removed. The cover is ignited to remove deposited carbon upon the under side. The crucible and cover are again cooled and weighed, the weight subtracted from that previously obtained, representing the fixed carbon.

When the bitumen carries mineral matter containing carbonates, the ash in the crucible is treated with a few c.cs. of a saturated solution of ammonium carbonate, dried, and ignited at a low heat to remove excess of carbonate and the corrected weight of ash obtained. The percentage of fixed carbon is calculated to the weight of the original sample, less the mineral matter obtained in the ashing. When notable amounts of "free carbon" are present in the bitumen, the results may be reported as fixed carbon less free carbon. The author, however, prefers to report the fixed carbon as obtained for the reason that the organic non-bituminous residues reported by the usual methods of extraction are probably seldom actual elemental carbon, but more often highly dehydrogenized hydrocarbon or hydrocarbon derivatives.

In cases where it is desired to obtain a fixed carbon figure apart from such non-bituminous matter, a portion of the soluble bitumen may be recovered from extraction for this purpose. In the hands of a single operator, uniform and consistent results may be obtained by this standard method, but skilled analysts are known to vary considerably upon check determinations. The heating value of the gas available in different localities is probably a large factor in this variation. Where certain natural gas is available for making this test, variations of 2 to 3% are known to result on this account. The quality of gas used is, of course, beyond the control of the analyst, although in the larger cities the heating value of artificial gas is fairly well regulated.

Aside from this, however, other considerations enter into the accuracy of the determinations—the exact size of the crucible, the tightness of the cover, freedom from draft, the position of the crucible in the flame and the exact size of the flame are all important factors. Considerable stress should be laid upon this latter. The standard method permits of variation of 2 cm. in the height of the inner cone and the exact length of the flame is limited only to a minimum. In the author's laboratory a bunsen burner of the Chaddock type is used for these determinations. This affords a protected and steady flame. The same burner is used for all determinations. The flame is adjusted to a scale laid off on a wood rod, graduated at a point level with 8 cm. and 20 cm. above the top of the burner. Before making the ignition, the rod is placed on the hip of the burner and the flame adjusted exactly in accordance with the graduations. A further advantage results from the use of a Chaddock burner in that the distance of the triangle (on the crown) above the top of the burner is necessarily always constant.

The importance of a more exact regulation of the flame may be illustrated by the following experiment wherein determinations were made upon the same sample under varying conditions of the flame, all other factors being the same, the crucible adjusted in each case ½ cm. above the tip of the inner cone:—

8 cm. cone, 20 cm. flame.....	13.59
6 cm. cone, full flame 25 cm. ...	12.64
8 cm. cone, 20 cm. flame	13.55
6 cm. cone, full flame 25 cm. ...	12.52

The determinations were made in the order given so that the effect of the manipulation in changing the flame, might be observed on the duplication of results. It is evident that very exact conditions of manipulation are necessary to obtain consistent results in these determinations. The discrepancies resulting from careless manipulation or even from variation of the flame with the limits given as standard may be sufficiently great to invalidate the correctness of deductions or proper interpretation of the results. It is believed that these factors are accountable for much of the lack of confidence in fixed carbon tests, and that with closer attention, a high degree of accuracy may be attained. Where conditions of gaseous fuel give comparatively high results, there should at least be no difficulty in making relatively correct and consistent determinations and specifications in such case can be modified and interpreted accordingly.

Some discussion of the derivation of the fixed carbon yielded by bitumens upon ignition is pertinent in considering the significance of fixed carbon and its consequent value in specifications. The character of the hydrocarbons present in the bitumen is a determining factor in their yield of fixed carbon. According to Richardson, this data shows the "relative proportions of carbon and hydrogen in the bitumen under examination. In the cases of paraffine hydrocarbons of the formula $C_n H_{2n} + 2$ no fixed carbon is left on ignition, while the amount increases with each diminution of the proportion of hydrogen to carbon, until in Grahamite as much as 50% is found, where the relation of carbon to hydrogen is as 8 to 1".

In other words, the yield of fixed carbon in bitumen is commensurate with the degree of condensation of the particular classes of hydrocarbons present in such bitumens. This condensation is brought about by natural agencies in the native bitumens. The manufacture of solid bitumen from native liquid bitumens involves the production of more of condensed aggregations of hydrocarbons as the resultant product. This is a function of the process used, and may be effected by means of de-

hydrogenization by air or sulphur, by oxygenation, by the splitting off of hydrocarbon, or merely by the concentration of more condensed hydrocarbon through the removal of lighter ones by distillation. Several means of condensation may be employed in the same process.

Remembering that fixed carbon is a measure of condensation of any given aggregation of asphalt hydrocarbons; and that such hydrocarbons may vary in degree of condensation to the extent that they become insoluble in certain fluxes, in carbon tetrachloride, and even in the usual solvents for bitumen, the value of this test will be further and more specifically discussed. It is the belief of the writer that the fixed carbon characteristics of various paving bitumens are significant in three particulars:—

First, as a means of identifying and classifying native bitumens; second, as a check upon the suitability of flux combinations with hard bitumens; and third, in the production of oil asphalts, as an important means of determining and controlling the quality and uniformity of the product. With reference to the value of fixed carbon as a means of identification of native bitumens, little need be said. In connection with other data, this feature affords an important item of identification.

As is well known, the Grahamites yield very high fixed carbon, ranging from 30% to 55%. The solid native asphalts used in the paving industry yield approximately 9% to 26% of fixed carbon. Gilsonites show 12% to 17%, the harder varieties giving the higher yield. Distinction between Gilsonite firsts and seconds and their quality is indicated by fixed carbon. The fixed carbon characteristics of the individual paving asphalts are fairly well defined for each kind and this feature affords a means of check of uniformity of such natural products and sometimes of the uniformity of their refinement. This function of the fixed carbon test is not directly pertinent to specifications so far as identification is concerned, but is of much value to the analyst in affording knowledge as to the material dealt with, and correlating with such knowledge a proper treatment in fluxing and handling.

Fixed carbon, as applied to native asphalts or partially fluxed refined products, has no place in specifications. The preparation of asphaltic cements or binders from hard, highly condensed bitumens is a matter of great importance. As previously indicated, such highly condensed products vary in solubility in the different kinds of fluxes available for softening purposes, some fluxes being totally unable to dissolve these products. The life and cementing powers of asphaltic binders are directly dependent upon the permanency and extent of solution of the harder in the liquid hydrocarbons present. The reference to solution is made here, not in the strict sense of the word, but by considering combinations of this character as colloidal systems of widely varying degrees of dispersion.

Certain of these highly condensed bitumens, such as pitch produced by cracking paraffine oils, are entirely insoluble in paraffine flux, so that only a mechanical mixture of oil and solid results from attempts to flux them. They are likewise insoluble in semi-asphaltic fluxes, but are dissolved by strictly asphaltic fluxes. With other highly condensed bitumens a granular or non-homogeneous compound results with paraffine fluxes, representing a minor degree of solubility, increasing generally as the flux or refined asphalts contain more of the heavy asphaltic malthenes which are of high solvent character. The effect of the presence of the heavy asphaltic malthenes is to "dilute" the highly condensed hydrocarbons, which yield high fixed carbon, thus producing bituminous cement of proportionately lower fixed carbon yield.

Some illustration of the variation of fixed carbon in cements in accordance with the character of the flux may be tabulated below (all cements between 50 and 60 penetration).

Fixed Carbon in Bituminous Cements with the following Fluxes:—

	Paraffine.	Illinois.	Texas.	Calif.	Character of Cement.
Grahamite	14.5%	...	...	...	Punky, non-homogeneous
"	...	13.3%	...	..	Dull, greasy, short.
"	...	..	12.4%	...	Bright.
"	...	..	..	12.4%	Bright, ductile.
Calif. "B"	16.3%	..	...	...	Dull, short granular.
"	...	15.2%	...	...	Dull, granular.
"	...	...	13.6%	...	Slightly granular.
"	...	...	...	12.6%	Homogeneous, ductile.
Cuban	13.9%	...	...	...	Dull, short
"	...	13.6%	...	...	Bright.
"	...	...	11.9%	...	Bright, ductile.
"	...	...	...	11.9%	Bright, ductile.

There is no mechanical method of measuring the condition of solution of these combinations, but the physical appearance, together with the ductility, gives a general index of this feature. The reference to "punky" indicates a putty-like condition, similar to shoe polish, and will be recognized by those familiar with bituminous products thus described. In the preceding illustration the same lot of flux was used throughout, so that this factor remained the same. In the use of California flux, the higher fixed carbon yield of this offsets, in some instances, the dilution of the hard bitumen.

In fluxing combinations, there is a generally improved condition of solution as the more asphaltic fluxes are used in combinations with the hard bitumens. The higher fixed carbon figures are associated with an imperfect state of solution, and the lower ones with more satisfactory combinations or greater degree of dispersion or, if the term might be used, with a better "grading" of hydrocarbons from heavy to light. The foregoing tabulation is not directed to any particular type of bituminous cement, but is given rather as illustrating the principles involved in this feature of the discussion.

It must not be assumed that a comparatively low fixed carbon yield without reference to other tests necessarily signifies in all cases a proper flux combination, but in dealing with hard bitumens fluxed back to paving consistency, the writer believes the reverse may be correctly stated, that a high yield of fixed carbon invariably signifies an improper fluxing, producing a cement of lower or impermanent binding value.

This may be often recognized by the physical appearance, homogeneity or ductility of the cement. If these latter characteristics remained permanent through ageing, it might be safe to place complete reliance upon them for determining these features, but as a matter of fact, combinations of the kind referred to are particularly liable to change and their appearance when fresh and especially their ductility is subject to great loss upon standing, so that the significance of a high fixed carbon content is of evident importance in such connection.

Fixed carbon, of course, varies with the consistency, naturally decreasing in a given combination as the amount of flux used and the consistency increases. It is evident that an apparently low fixed carbon yield obtained at a high consistency may be in reality excessive. For example, a fixed carbon yield of 12% in a fluxed cement may not appear excessive when considered alone, but if associated with consistency of 200 penetration would be of undoubted significance. Therefore, this must be interpreted in accordance with consistency, and the correct significance may be conveniently arrived at by preparing

a curve for the given combination covering a sufficiently wide range of consistency to give the relationship desired. Such a curve is given hereinafter for an oil asphalt cement.

Where specifications are so drawn as to cover the character of fluxes used in the cement and carefully prescribe the kinds and amount which may be employed under various conditions, a fixed carbon requirement is hardly necessary. However, very large quantities of prepared cements and binders for bituminous roads and pavements are now purchased and used under such conditions as to make it impracticable to govern the fluxing operations directly. Under such conditions, particularly when a number of bitumens, rather than a single combination may be compounded into the marketed product, the value of a fixed carbon requirement in the specification as applied to the cement, becomes apparent.

The foregoing discussion has referred only to conditions in which hard, highly condensed bitumens are fluxed to paving consistency. In dealing with asphaltic products brought to grade by distillation from liquid native bitumens, a somewhat different and more important significance may be attached to fixed carbon. As has

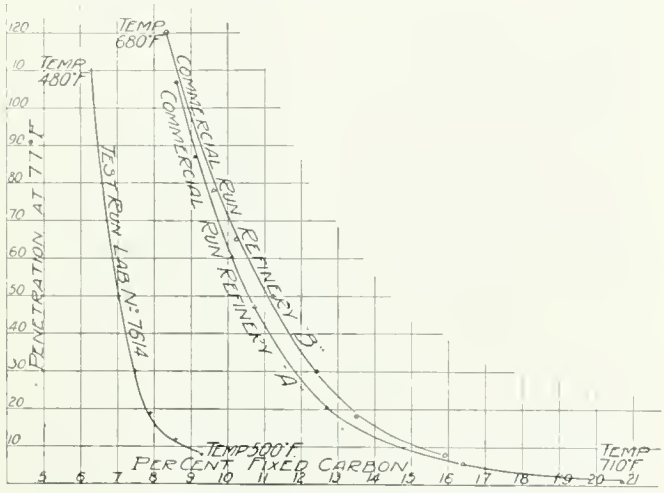

Fig. 1.

been previously stated, the formation of this class of materials involves the production of more condensed products than the liquid bitumen from which they are made. In the distillation of liquid bitumens for asphalt, it is recognized that it is desirable to avoid cracking or the splitting off of hydrocarbon so far as possible, in order that the residual may retain its binding strength and permanency to the greatest possible useful extent.

The splitting off of hydrocarbon may take place to a comparatively slight degree, or it may go so far as to evidence itself in the production of "carbenes" or even of insoluble hydrocarbon and free carbon. For a bitumen of a given character, the splitting off of hydrocarbon with subsequent condensation evidences itself by greater fixed carbon yield. It follows, therefore, that the yield of fixed carbon in solid bitumens produced by distillation, becomes an index of the extent to which the splitting off reaction takes place as compared with a simple concentrating of condensed hydrocarbons already present in the crude bitumen. Fixed carbon thereby affords an index of the severity of heat treatment, ranging from evidences of lesser degree to the accompaniment by carbenes or insoluble hydrocarbon or free carbon.

Where solid bitumens are produced by condensation of residum with air, without distillation taking place, a normal fixed carbon content will result from such condensation, greater, of course, than that of the residuum. If, however, the residuum be cracked or partially decomposed in preparation, and abnormally higher fixed carbon will result; likewise if the air treatment be so conducted as to result in distillation by splitting up of hydrocarbon, the product will show higher yield of fixed carbon.

In order to illustrate the effect of heat treatment in the distillation of native liquid bitumen, the writer has prepared data giving the range of fixed carbon figures upon samples taken at various intervals from a still during a commercial run of residual asphalt under known temperature conditions. A lot of the same crude as used in this run was subjected to careful distillation in a laboratory still under conditions, including lower temperature, which minimized, if not entirely avoided, all splitting up or cracking action.

The results are given here in graphical form in Fig. 1, wherein the commercial run referred to is designated refinery "A." The results obtained upon a series of commercial samples from refinery "B" are likewise given, although no data was obtainable in connection with these samples as to temperature conditions during their preparation.

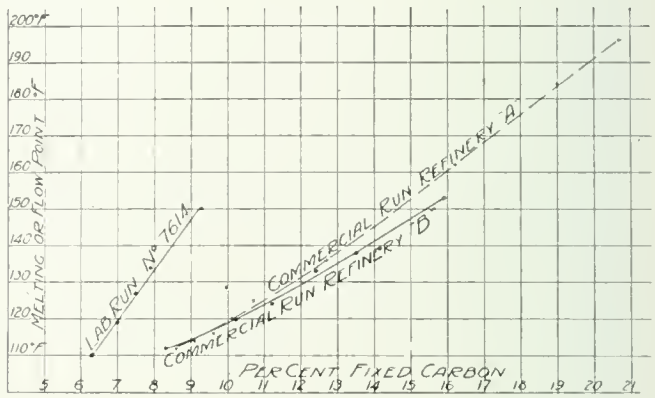

Fig. 2.

Fig. 1 gives the relationship between consistency and fixed carbon. A sharp turn in the curves is noted at the harder consistencies, which might be construed as representing conditions of greater severity. This, however, is not strictly the case but is due rather to the imperfection of the penetration test which does not accurately measure relative hardness, particularly at the low penetrations.

In Fig. 2, the flow or melting point relationship with fixed carbon is given, the former representing relative hardness to a more accurate extent. It is noted that these latter curves approach a straight line, indicating nearly direct variation between these elements. It is apparent that a difference of some 200° F. in heat treatment of the bitumen results in a showing of materially different fixed carbon characteristics in the resulting products.

At the low temperatures the distillation follows closely to a true concentration of condensed hydrocarbons originally present in the crude. The difference between this and the commercial run is evidently represented by additional condensation due to the higher heat treatment in splitting off hydrocarbon.

The writer considers the fixed carbon characteristics of the commercial runs given as representing the better grades of this kind of product now available commercially upon the market. As an illustration of the effect of this

action to an undesirable degree, are given a few analyses of the residual products of like asphaltic base crude, the first two of which were produced from the same crude as in the preparation of samples of series "A."

Pen.	42	46	80	41	26	22	46	32
Fxd. C	14.7%	14.3%	16.8%	16.9%	16 6%	20.0%	17.0%	18.6%
Sol CS_2	99.8%	99.3%	99.7%	99.7%	99.7%	97.2%	99.0%	98.0%
Sol CCl_4	98.8%	96.5%	96.0%	97.9%	96.9%	86.6%	94.4%	90.9%
Ductility	115+cm	110+cm	110+cm	60.0cm	55.0cm	18.0cm	7.0cm	4.5cm

Of the above cements, the third has a history of service test. It was laid in a sheet pavement in 1910 on a residence street. The pavement marked well in 1910 and passed through the winter with one crack. The following summer it was harder but still marked. It cracked usually severely in the winter of 1911. In the summer of 1912 it was very hard in the hottest weather but showed freely the calk marks of previous traffic, the pavement being too stiff to iron out. The general appearance indicated very rapid hardening of the cement.

Inspection of these results shows the effect of condensation in various degrees to the final stages where the material has retained but little binding value and is characterized by little ductility, by the presence of considerable amounts of carbenes and by insoluble carbonaceous matter. It will be of interest to locate the fixed carbon points of these samples in comparison with the curves given for the acceptable grades of the commercial article.

Attention may be called at this point to the fact that some crude oils normally give rise to asphaltic residues of much higher fixed carbon yield than the materials used in the foregoing illustration. This is possibly due to an originally large content of highly condensed hydrocarbons, and to the nature of the particular hydrocarbons present. In such cases a relatively high fixed carbon content in the residual product is not necessarily related to the severity of heat treatment and in dealing with such residuals, specifications and proper interpretation of fixed carbon characteristics must be based upon data obtained by careful run of the crude under known conditions.

The effect of the character of crude upon the fixed carbon yield of product prepared therefrom, is illustrated upon two samples treated by test runs as previously illustrated.

	Gravity.	Crude Fixed Carbon.	Fixed Carbon in Distillation.	Fixed Carbon in Product.	Yield Product.
Crude A	12.5°Be	3.7%	.02%	6.3%	60%
Crude M	18.0°Be	7.5%	...	15.8%	50%

It will be noted that by careful distillation the formation of condensation products is small and that the value of 15.8% of fixed carbon obtained in the residual of crude "M" is quite normal for this, although it would not be so for crude "A."

It will be seen that the determination of fixed carbon in asphalts produced by distillation, affords an important means of control of the quality, uniformity and care used in preparation of the product. The excess of fixed carbon yield above that normally resulting by concentration from the condensed hydrocarbons present in the crude, is a measure of condensation produced by the effects of the heat treatment in splitting off of hydrocarbon.

It is apparent that the best practice should limit this action to the minimum and that specifications should control this by a fixed carbon limit within which the product will retain to a useful and permanent extent, the qualities necessary for pavement and road construction.

It must be understood that the fixed carbon test, like others employed in the examination of bitumens, must be interpreted and applied in specifications upon the basis of a broad understanding of the relationship between the various chemical and physical characteristics of paving bitumens and their origin and methods of preparation for the market.

OIL AND GAS IN WESTERN ALBERTA.

The Geological Survey has received a sample of the oil recently struck by the Calgary Petroleum Products Company at a well situated at Black Diamond, sixteen miles west of Okotoks, Alta. This oil was struck at a depth of about 1,560 feet. It is what is technically known as a "white oil," being transparent and of an amber color. It is phenomenally light for a natural mineral oil, having a specific gravity of about 62 Baume. Evidently it consists largely of gasoline. In fact it has been successfully used in its raw state in place of gasoline in an automobile.

White oils are rarely found in quantity. They would appear to be the result of filtration through clay strata, under pressure, of the lighter portions of ordinary petroleum. That this has occurred in the present instance is made probable by the fact that at a higher horizon in this well a flow of gas of 2,000,000 feet a day, was struck. This gas is also peculiar in the large amount of gasoline it contains. It probably represents a further stage in the process of filtration.

The amount of oil present has not yet been determined, so that the commercial value of the strike is still unproved. If the amount of gas encountered in the higher level is any criterion, this may prove to be the exceptional case and a considerable quantity of oil, for a white oil, be obtained.

Whether oil is present in large quantities or not, the strike is of importance, as the white oils are usually found only in the vicinity of large bodies of the ordinary petroleum. Thus it is an excellent indicator.

Mr. D. B. Dowling, of the Geological Survey, who visited the well shortly before the strike was made, reports that the well is located on an anticline, in shales of the Pierre formation, and that the oil was encountered in underlying Belly River beds. On either side of the anticline overlying Edmonton beds are exposed. Going eastward, therefore, the covering will rapidly thicken. Westward toward Moose Mountain, according to the work of D. D. Cairnes, of the Survey, the formations are folded into a number of anticlines, bringing lower formations to the surface, and in Moose Mountain faults are encountered. Between this faulted ground and the well are several anticlines where prospecting for oil might be undertaken. These anticlines probably run in the direction of the main structural lines, that is, roughly parallel to the mountain ranges. Mr. D. B. Dowling, of the Geological Survey, is now in the field, having been commissioned by the Director to examine the well and make a study of the geology of the district.

It is not often that a complete electric light station sails away after having done good service to a town. Such an unusual happening is reported from the Township of Ocos, in Guatemala, which, having enjoyed the benefits of electric lighting, has unwillingly reverted to oil lamps, its powerhouse having gone to sea. Four years ago a liner was imprisoned in the lagoon without suffering any damage. An enterprising engineer thereupon used the ship's dynamos for supplying the whole township with current for lighting. The scheme was a great success until a salvage company appeared. The connecting cables were severed, the vessel went back to sea, and Ocos was temporarily left in darkness.

OVER-OXIDATION OF STEEL.

MESSRS. W. R. Shimer and F. O. Kichline, in a paper read before the New York meeting of the American Institute of Mining Engineers, describe some investigations carried out for the purpose of studying, both by chemical and metallographical means, the extent of over-oxidation of steel that can be accomplished by excessive over-blowing in a Bessemer converter. In addition they give some results of basic open-hearth and crucible steels.

The experiments were carried on in a Bessemer converter blowing steel for the duplex process. The hot metal used, with one exception, had the following composition:—*C*, 3.50 per cent.; *Mn*, 0.70 per cent.; *P*, 0.450 per cent.; *S*, 0.050 per cent.; *Si*, 1.20 per cent.

In the basic open-hearth heat a test sample was taken just before adding ferro-manganese. The bath had been boiled down "flat" and held for some time. The following is the analysis:—*C*, 0.05 per cent.; *Mn*, 0.05 per cent.; *P*, 0.023 per cent.; *S*, 0.055 per cent.; *O*, 0.024 per cent. It will be noted that the oxygen content of this heat is low, in spite of the fact that the heat was boiled down flat and held some time at a high temperature, thereby affording the best conditions for over-oxidation. Results on finished open-hearth steel are of interest; the drillings for these determinations were not taken from test blocks, but from the finished product.

Rail Steel.

Heat No.	Oxygen. Per cent.
E—21,276	0.018
E—17,244	0.015 0.016
E—22,377	0.018
E—17,441	0.017
E—21,428	0.019
E—24,202	0.019
E—26,065	0.017

Structural Steel (about 0.19 per cent. C.)

Heat No.	Oxygen. Per cent.
E—14,096	0.024
E—17,104	0.022
E—22,068	0.019
E—22,277	0.015
E—24,063	0.014

Oxygen determinations were run on a few 0.60 per cent. carbon crucible steels, and showed the following oxygen contents:—

Sample No. 1.—Test dipped out of a 90-lb. crucible and cast into a small test block; oxygen, 0.014 per cent.

Sample No. 2.—Test dipped out of a 1-ton ladle; same heat as sample No. 1; oxygen, 0.014 per cent.

Sample No. 3.—Finished rolled bar; oxygen, 0.010 per cent.

Sample No. 4.—Rolled bar picked out at random from the stock rack; oxygen, 0.010 per cent.

Samples 1 and 2 were dipped out of the bath and cast into small moulds, and were, therefore, somewhat porous, which no doubt accounts for their showing slightly higher oxygen than the finished bars, which were solid.

The results obtained from converter metal may be summarized as follows. Every effort at over-oxidation was made, both by over-blowing and by ore addition:—

The highest oxygen contents obtained by over-blowing, were 0.074 (in Test 2); 0.064 per cent. (in Test 8) and 0.049 (in Test 11), notwithstanding that the samples were taken immediately, in order to get the highest oxygen possible. Also the samples were cooled quickly so that no gas could escape during casting.

While oxidizing with ore, we obtained 0.029, 0.028 and 0.033 per cent. oxygen, by taking test samples immediately after the ore began working through the metal. When time was allowed for the oxygen to escape after the ore addition, a content of 0.017 per cent. oxygen was found.

A basic open-hearth heat, under oxidizing conditions, gave only 0.024 per cent. oxygen.

It appears that either an unfinished heat or an over-ored heat will produce slag inclusions, such as manganese silicate, instead of iron oxide.

From these results, considering the manner in which they were taken, we may conclude that excessive oxygen leaves a bath of molten steel in a very short time. Also that deoxidation is readily effected by the addition of hot metal.

Under the same conditions, the higher the carbon the lower the oxygen.

Finally, it seems highly improbable that, under the usual conditions of Bessemer and open-hearth practice, with the addition of recarburizers, that a steel of over 0.030 per cent. oxygen can be obtained, and that the highest obtainable under any conditions, without recarburizing, can hardly be over 0.075 per cent. Results higher than this must be from drillings improperly taken, or from oxidation that occurred during pouring.

NEW YORK'S NEW CANAL.

Progress on New York State Barge Canal furnished the subject for a lecture given on October 30th by State Engineer John A. Bensel before the New York State Waterways Association Convention. Mr. Bensel stated that at present more than 250 miles of the canal are completed to the dimension size, and all of the more important structures are more than 80 per cent. finished. The construction work of the past year has called for an expenditure of $13,000,000; and the total work up to date, for about $64,000,000; while the remaining contracts will have need of an additional disbursement of $82,000,000. Mr. Bensel urged particularly in his lecture that the utmost care be taken to obtain the best possible management for the terminals in New York, Brooklyn, Utica, Buffalo, Albany and all other cities. Work on these is progressing very rapidly. About 35 contracts have been let, and the Albany terminal is already in use in a commercial way.

GERMAN IRON AND STEEL PRODUCTION.

According to the returns of the Association of German Iron and Steel Manufacturers, the total production of raw iron in Germany and Luxemburg during the first six months of 1913 amounted to 9,567,666 metric tons, as compared with 8,564,988 during the first six months of 1912. The production of foundry pig increased from 1,581,754 tons in 1912 to 1,812,434 in 1913; of Thomas iron from 5,482,432 to 6,049,330; and of steel and spiegel iron from 1,037,902 to 1,269,563. The production of Bessemer and puddle decreased as compared with 1912, the former from 193,763 to 174,483 tons and the latter from 269,137 to 261,856 tons.

ENGINEERS AS CITIZENS.

It has frequently been suggested that more of the meetings of the various branches of different engineering societies be devoted to the discussion of civic engineering problems, not necessarily those only that are immediately concerned with an engineer's particular technical work, but problems of a more or less general engineering nature. This suggestion was recalled and strongly upheld by Mr. R. D. Mershon at a joint meeting of the Western Society of Engineers and the American Institute of Electrical Engineers in Chicago, his opinion being that individuals taking part in such discussions would be almost likely to bring to bear in public affairs the conclusions there arrived at, and the ideas that would crystallize in their own minds as a result of such discussions.

One feature of the engineer's life that should be more strongly emphasized and urged by engineering societies is this desirability of his taking a greater part than he has done heretofore, in public affairs, especially in the civic affairs of the immediate community. Practically all economical problems are engineering problems, and the engineer cannot avoid taking his own responsible share in their solution.

The engineer's excuse is that he is an exceedingly busy man, and the result is that unless he has the opportunities made fairly easy for him, he is not likely to get out and interest himself in matters respecting the city's welfare. Those who read the address of Dr. Swain, presented at the Ottawa meeting of the American Society of Civil Engineers last June, and reproduced in our issues of June 26th and July 3rd, doubtless profited a good deal by his illustrations of the personal responsibility which the engineer owes to the community. As to the engineer's capabilities in this direction, the speaker stated:

"If there is anything in training and experience, may we not believe that engineers, as a class, have the training, temper and experience, which will best enable men to judge sanely and solve wisely the social problems that confront us?" When one realizes that the problem of administering the affairs of a city involves the preservation of the health, safety, property, and order of the community, and are, therefore, dominantly of an engineering character, it appears strange that we do not find more of our engineers occupying positions of greater responsibility in the administration of civic affairs.

In some European countries the method of handling civic affairs is quite different from the method in this country. In Germany, the position of mayor is not elective. The work is regarded as a profession, and the individual is not elected, but employed. Recently there was an advertisement for a mayor in one of the German technical papers, and it specified that he should be an engineer.

The findings would be interesting if one were to study the relations between engineering interests and social conditions in general. It is stated, for example, that Illinois, one of the great agricultural states, has progressed to a point where 49 per cent. of its people get their livelihood from something connected with engineering interests. It would be interesting, therefore, to parallel with this, some measure of the attention which engineers pay to legislative and constructive action, public welfare, and social problems of that nature; and it is certain that there has not been enough of co-operation on his part in the past. Although there are no men better qualified, one is safe in stating that there are none that

fall farther behind in such obligations than do the engineers.

THE FIXED CARBON TEST.

Specifications have been issued this week by the city of Toronto for the supply of asphalt for 1914. Practically the same specifications are retained which were used for this year's supply, the clause limiting the maximum amount of fixed carbon to fifteen per cent. remaining the same as in the 1913 specifications.

In view of the differences of opinion regarding the value of the fixed carbon test, as indicated by the series of articles by various prominent chemists now appearing in *The Canadian Engineer*, thorough experiments will be made and much research work done during the coming year by the chemical and engineering staffs of Toronto, in order to determine whether the test should be retained in, or excluded from, the specifications, or retained in a modified form. It was felt by the Department of Works, however, that so little time remained for such an investigation this year, that the 1913 specifications would have to be used again for the 1914 supply, but that the experiments made during 1914 might result in considerable change in the 1915 specifications.

The objections to Mr. Kirschbraun's suggestion that were made by a prominent municipal engineer who was shown an advance proof of Mr. Kirschbraun's article, which appears in this week's issue, were that it would be impracticable to carry out the suggestions made in the article, as no city could be sure that it was securing the refinement from a certain lot of crude, even if it were able to secure a dependable analysis of that crude, nor would they know the percentage of refinement. That, of course, bears out the very argument urged by many chemists against the inclusion of the fixed carbon test in specifications, namely, that this test cannot be included in such a way that it will be both fair to the contractors tendering and also enforcible in a practicable way.

EDITORIAL COMMENT.

The transformation wrought in the geography of the world by the construction of the Panama Canal, and the consequent changes to be expected in the world's commerce, involve preparations in the form of new harbors, new docks, and additional railways, remarkable alike in extent and in rapidity of construction. Contemplated as a whole, and when the element of time is taken into account, these undertakings constitute an engineering project of variety and magnitude unprecedented in the history of transport development.

* * * *

The Dominion Government has under consideration some new regulations to govern the development of the oil resources of Western Canada. It is reported that Mr. Cunningham Craig, of Birmingham, and Prof. Chadwick, of London, Eng., have investigated conditions as they exist, and that a draft of new regulations has been prepared and at present their applicability is being considered by the Department of the Interior. It is also stated that western men have forwarded a suggestion that the old regulations be revised so that for purposes of development claims may be grouped instead of requiring each claim to be singly developed.

A discussion on the causes of the deterioration of fire-bricks during use was recently presented by Mr. Geo. Rigg, in which the conclusion is reached that, other things being equal, the resistance to the action of corrosive slags and gases is greater the more compact and close-textured the brick is found to be. Spalling of close-textured brick is due to the use of unsuitable clay, or poor workmanship, or both. It is possible to prepare close-textured fire-brick containing considerable amounts of coarse material, provided that sufficient care be taken in sizing the grog, so that the interstices between the larger fragments shall be filled as completely as possible by smaller fragments.

LETTERS TO THE EDITOR.

Features of the Springfield (O.) Sewage Disposal Plant.

Sir,—Referring to the article "A Departure from Common Practice in Sewage Disposal" in your issue of October 23, 1913, we beg to call attention to the fact that the so-called "vertical circulation" is neither new nor original with Mr. Potter, as it is an essential feature of the process set forth in our Travis and Ault (Hampton Tank) patent, application for which was filed September 13, 1910. The "Adjustable weir" which he uses for the regulation of this "vertical circulation" is also embodied in another of our applications for patents and follows the lines of explanations and information given by our engineer to Mr. Potter while he was designing the Springfield plant.

We notified the mayor of Springfield on October 25, 1913, and Mr. Potter on October 27, 1913, that the tanks at Springfield were an infringement on the Cameron septic process patent and of the Travis and Ault (Hampton Tank) patent, both of which are controlled by this company, and that we should take all necessary steps to protect our rights.

We call attention to these points that engineers and municipalities may know the facts and avoid any unintentional infringement of our patent rights.

STERILIZATION COMPANY.

Newark, N.J., Nov. 8th, 1913.

* * * *

[Upon receipt of the above the attention of Mr. Potter, who submitted the article referred to, was called to it, and his reply is as follows:—Ed.]

Sir,—Answering the letter of November 8th from the Sterilization Company, of Newark, N.J., I regret that I am compelled to say that there are statements in that letter and in letters to which they refer which are at variance with the facts.

The writer first saw a representative of this company a month after the designs for Springfield were completed. These designs were completed before the middle of February, 1912. The plans were then taken to Springfield by the writer in person for submission to the city authorities. The completion of the drafting of the finished plans took two weeks longer and were forwarded to the writer (then in the southwest) on March 1, 1912. These plans were finally approved by the municipal authorities at Springfield on March 15th, and the work ordered advertised for April 4th.

On March 1st the writer received a letter under date of February 23rd from the Sterilization Company, admitting that they were informed by his office that the plans

were based upon other designs than theirs, and requesting consideration of their method.

The writer returned to New York on March 19th, after an absence of a month, and the following day a representative of the Sterilization Company called. For the first time the writer conferred with this company in reference to their system and its application at Springfield. They were advised that the Springfield designs would not be altered, but in response to their request were informed that if they desired to submit an alternate bid based upon their own plans at the public letting on April 4th, such bid would be given consideration if accompanied by guarantees of efficiency.

On the 26th of March a sketch plan was submitted by the Sterilization Company, showing what they proposed to offer, and on the 29th of March a letter was received from them giving a bill of material required for their plan. They found that it was impossible for them to submit a proposition on the sewage disposal plant as a whole, but requested the submission of their tank plans to general contractors.

Discussing the merits of the contention of the Sterilization Company that the Springfield tank is an infringement upon their patents, the writer desires to point out that there is a distinct difference between the Hampton tank and the Springfield tanks. In the former, from ten to twenty per cent. of the entire sewage flow travels horizontally through the digestion chamber towards the outlet setting up a substantial disturbance throughout the digestion chamber where quiescence is more desirable. The debouchment of over ten per cent. of the flow from the digestion chamber very seriously interferes with the ultimate reduction of the sludge. In the Springfield tanks openings are placed along the pipe provided to draw off the relatively small quantity of liquid (less than two per cent.) from the digestion chamber needed to set up a downward circulation in the settling tank.

Furthermore, the discharge of from ten per cent. to twenty per cent. of the liquid from the digestion chamber in the Hampton tank will require separate treatment of the two effluents, otherwise the efficiency of subsequent treatment, if both flows re-unite, is impaired. In the Springfield tank, on the other hand, the small flow from the digestion chamber cannot seriously affect the effluent from the settling tank. In the Springfield tank there is absolutely no horizontal flow towards the outlet end of the tank.

From a structural standpoint, the Springfield tank as built is more effective than other types, in that while the time of retention in the settling tank is the same as in other tanks, the velocity of flow in the tanks is from half to two-thirds less, a condition tending to produce a greater deposition of solids.

It is to be hoped that this discussion will eventually lead to some definite conclusion as to this much-mooted question of sewage disposal patent infringement. It should be noted that this company alleges infringement of the Cameron septic tank patents controlled by them. According to the Winchester, Ky., case, the admission of the use of a two-story tank is considered by the Sterilization Company as *prima facie* evidence of an infringement of patents now controlled by them. The payment to Dr. Imhoff of his license fee where his tank is used, does not give immunity from suit by the Sterilization Company as owners of the Cameron process.

In view of the charge of the Sterilization Company that the Springfield tanks are an infringement of the Cameron patent, the following editorial comment from the "Engineering News," Feb. 6th, 1913, is of interest:—

"In its decision of Jan. 20, 1913, the U.S. Supreme Court declared in unmistakable terms that the United States patent on the Cameron septic tank expired on Nov. 8, 1909, 'with the British patent for the same invention.' To sustain any claim to the contrary, it would therefore seem to be necessary to get the Supreme Court to reverse its decision, either on a re-hearing of this case or by carrying some other case to the U.S. Supreme Court."

Yours truly,

ALEXANDER POTTER.

New York, Nov. 18th, 1913.

THE EFFECT OF DRILLED HOLES ON STRENGTH OF STRUCTURAL STEEL.*

A series of experiments to determine the effect on the elastic limit and tensile strength of structural steel of drilling and punching holes is described by C. Birault, chief of the department of testing materials of l'Ecole Centrale, Paris. In the first series of experiments, three bars were cut from one piece of steel. One was ruptured in its original condition; the second after perforation with two holes by drilling, and the third, after perforation with two holes by punching. The holes in each case were 15 mm. diameter, spaced three diameters centre to centre. The plain bar elongated much further than the other two, while the bar with drilled holes elongated more than that with punched holes. The fracture of the punched bar did not take place along the diameter of the holes, due probably to fissures caused by the action of the punch. The drilled holes broke at their central diameters.

The following is an average of the results of three sets of tests:—

Plain bar, elastic limit, 24.5 kg.; tensile strength, 40.06 kg.; drilled bar, elastic limit, 30.03 kg.; tensile strength, 45.4 gk.; punched bar, elastic limit, 33.3 kg.; tensile strength, 37.3 kg.

In each case, the elastic limit was higher in the perforated bars than in the plain bars, with the increase in favor of the punched holes over drilled holes, while the reverse is true as regards tensile strength. The bars with drilled holes have 12.3 per cent. greater average elastic limit and 9.2 per cent. greater average strength than plain bars of the same steel. In the case of punched bars, the elastic limit increased 13.5 per cent. and the tensile strength 8 per cent. compared with plain bars of the same steel.

In the second series of tests, bars were perforated with driled holes of various diameters to determine the effect on the physical properties of the steel compared with plain bars of the same steel. Holes 11, 8 and 6 mm. diameter, were drilled and tested as a comparison against the plain steel. The following elastic limits were shown:

Plain bar, 28.9 kg.; 11 mm. holes, 32.3 kg.; 8 mm. holes, 32.0 kg.; 6 mm. holes, 33.7 kg.

The tensile strength of the various bars tested was as follows: Plain bar, 45.2 kg.; 11 mm. holes, 50.4 kg.; 8 mm. holes, 48.7 kg.; 6 mm. holes, 53.0 kg.

As to why there are such increases in the physical properties of bars with drilled holes over plain bars, the

*Abstracted from Le Genie Civil, July 19, 1913.

author states that in bringing into contact the fractured ends of the plain bars, it is found that there is a hollow space near the centre where the metal has evidently drawn away first, the break then proceeding gradually to the two sides. If, however, the metal is perforated with holes that are smooth, as in drilled holes, and not having fissures as in punched ones, this tendency of the metal to separate is removed, and the mean resistance to rupture is more uniform.

The author claims to have established the fact that the resistance to rupture of solid bars and perforated bars of the same metal is not proportional to the sections of the bars, proper allowance being made for the perforations. Section for section the advantage is in favor of the perforated bars, if the holes have been drilled and not punched. The holes weaken the steel much less than would be expected, provided care is taken to drill the holes, or to ream them after they have been punched.

THE TIMISKAMING DAM OF THE OTTAWA RIVER STORAGE SYSTEM.

By J. A. MacDonald, Ottawa, Ont.

IN the Aug. 7th, 1913, issue of *The Canadian Engineer* an article entitled "The Ottawa River Storage System" outlined the objects of the extensive conservation works which are being built by the Department of Public Works, Canada, in the Upper Ottawa Basin. The reader's attention is directed to that article for general information respecting this development, and for the illustrations, several of which refer to the following description of the design and construction of one of the units of the system, viz., the dam at the outlet of Timiskaming Lake.

At Mattawa, 300 miles above Montreal, which is the discharge point of the Timiskaming basin, including part of Timagami and Kipawa Lake basins (see Fig. 1), the yearly mean flow is 25,000 cubic feet per second from an area of 30,300 square mile feet. The Timiskaming basin, including everything from the source of the Quinze down to Mattawa, has an area of 20,000 square miles.

The Timiskaming storage dam, which is situated at the foot of Timiskaming Lake, was designed for the purpose of emptying the lake to its lowest level before floods and then filling it to the highest attainable stage for winter consumption. The lake itself stretches from Timiskaming Station to New Liskeard, Ont., and Murray, Que., a distance of 60 miles. It is navigable by steamboat and, in fact, until the Timiskaming and Northern Ontario Railway was built, afforded the only transport up to Ville-Marie and to the clay belt of Northern Ontario.

The immediate drainage is very limited as the shores are high and steep, but this lake receives all the drainage of the Kipawa, Quinze, Expanse, Blanche, and Montreal systems, a total area of 18,000 square miles down to Timiskaming Station. The lake is narrow, practically a river for 12 miles up to Opimaka Narrows, then about a mile in width for 30 miles further up to Silver Centre, where it becomes wider until a maximum width is attained at the head of the lake between Haileybury and Murray.

Outlet of Timiskaming.—While there are many inlets to this lake, the only outlet is at its south end, where, through the Long Sault Rapids, the waters fall 59 feet in six miles into Seven League Lake, and thence by three other rapids, descends 30 feet more to Mattawa. The discharge averages 110,000 c.f.s. during May, but it shrinks to about 10,000 at low stages during winter time.

18-in. and 15 by 15-in. stop-logs. These sluiceways are illustrated in Figs. 2, 3 and 4. The still platform is at elevation 570 or 19 feet below standard level of reservoir. It would have been preferable to have had the sill 5 feet lower, but the excavation necessary to cut down the approach channel would have doubled the cost.

Between the island and Ontario shore, the width was about 400 feet, so the design was made for 16 sluiceways each 20 feet wide with a pier 5 feet wide between. These are illustrated in Fig. 3, of the article to which reference has already been made. The piers have recesses to hold a movable curtain wall formed by horizontal timbers, 18 inches square, that can be hoisted out one by one. This is a removable dam and during spring floods all the timbers will be lifted out, leaving a larger exit than under natural conditions, because the Ontario channel has been

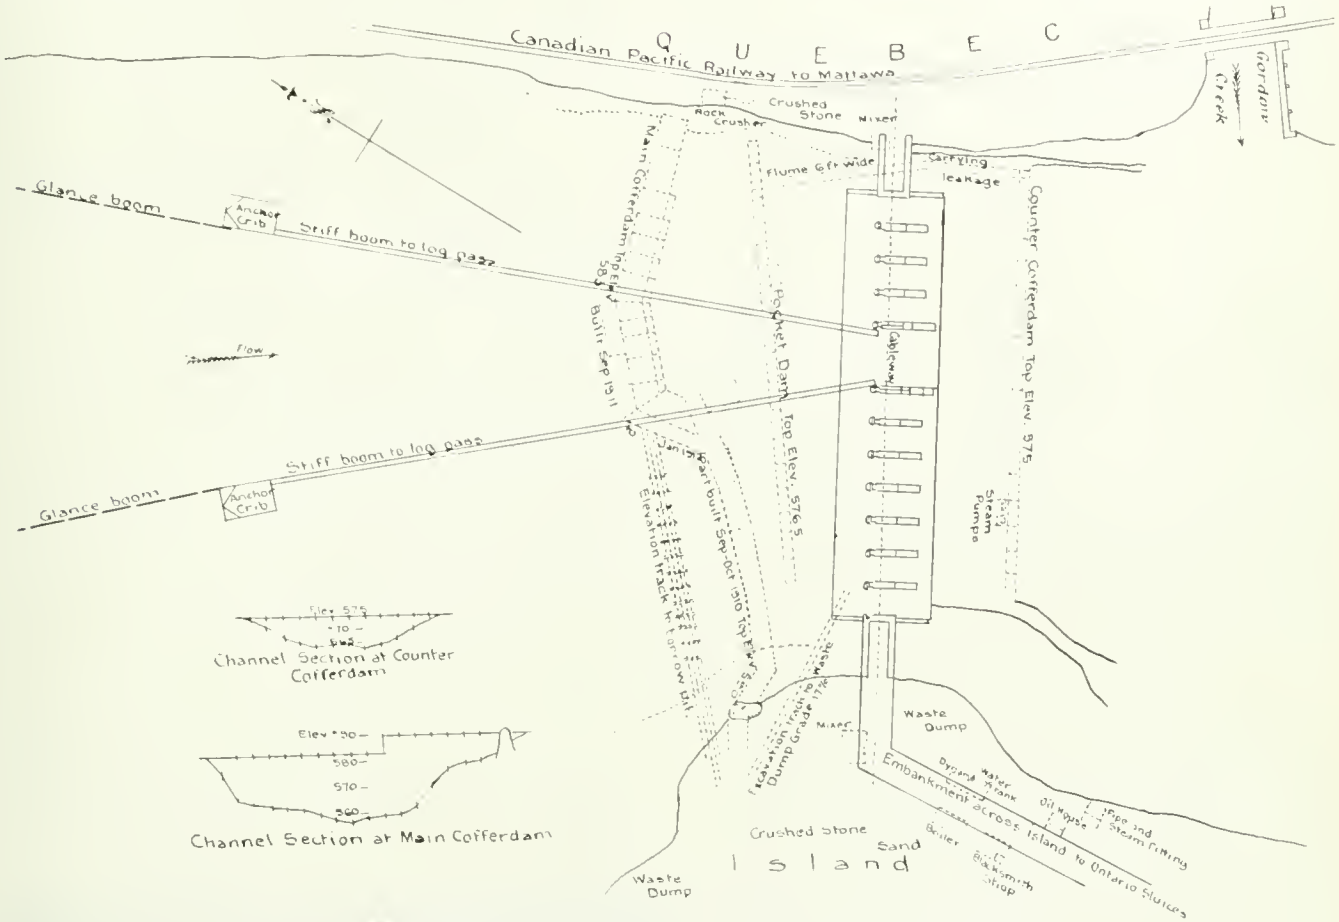

Fig. 2.—Arrangement of Regulation Work in the Quebec Channel.

The holding of Lake Timiskaming at a maintained surface level of 588, which was considered to be the best level to prevent damage by flooding, gives a storage depth of 20 feet. The sluiceways will thus drain down the lake to that amount between and augment the low water flow, for at least 150 days, by about 4,000 c.f.s.

Design of Sluiceways.—For the Quebec channel the design for a boulder foundation consisted of a monolithic slab of concrete 3 feet thick, extending from 22 to 26 feet up-stream to 12 feet down-stream, to be built across the river with a cut-off wall of varying depth along the up-stream and down-stream edges. The upper cut-off has been built 10 feet and that down-stream 5 feet in depth.

Upon this platform rest 11 piers 20 feet apart and two U-shaped abutments 48½ by 25½ feet with 5 foot walls. The sluiceways are arranged to be closed by 18 by

deepened. To draw off the lower layer of storage during March, however, deeper sluice openings are required, and so advantage of the depth in the Quebec Channel was taken to place those sills at elevation 565, or 5 feet lower.

The minimum discharge through the Timiskaming sluices should be about 20,000 c.f.s. and lake surface must be at 573.95 elevation to discharge the total amount.

As designed, the lake surface can only be drawn down to elevation 573.95, instead of elevation 573.05, so a layer 0.9 feet thick is rendered unavoidable. However, lowering the Ontario Channel would double the cost, and such an outlay was not warranted.

The Foundation.—The foundation of the sluices is shown in the accompanying Fig. 3. It consists of a concrete platform 3 feet thick, strong enough to support a pier. To prevent a scour, a cut-off was made 10 feet deep

across the upper face, and another 10 feet deep along the lower side. In addition a concrete apron, 25 ft. wide protects the bottom from scouring under the driving water at entry, and a 50-foot apron below prevents wearing away of material by the rapidly flowing water.

For the cofferdam, soundings were taken to determine the shape of the river bottom upon which the cribs were to rest and the bottom of each crib was built to fit its particular place. This was a difficult matter, as over the whole area there were nests of large glacial boulders 8 and 10 feet in diameter, and closely packed in a layer of gravel averaging 3 feet in depth above river sand.

The foundation generally was a mass of boulders, as stated, embedded in compact sand, but 25% of the area toward the island side was sand with only occasional boulders. This was saturated with water which seeped through over practically its entire surface and the sand readily drifted off in the current when disturbed. To cover this with a concrete slab was difficult as scouring constantly took place along the edges. It was found after trial that it was impracticable to drive sheet piling owing to the stones that were encountered.

Owing to the slow rate of excavation it proved best to first lay the foundation slab in unconnected pieces and

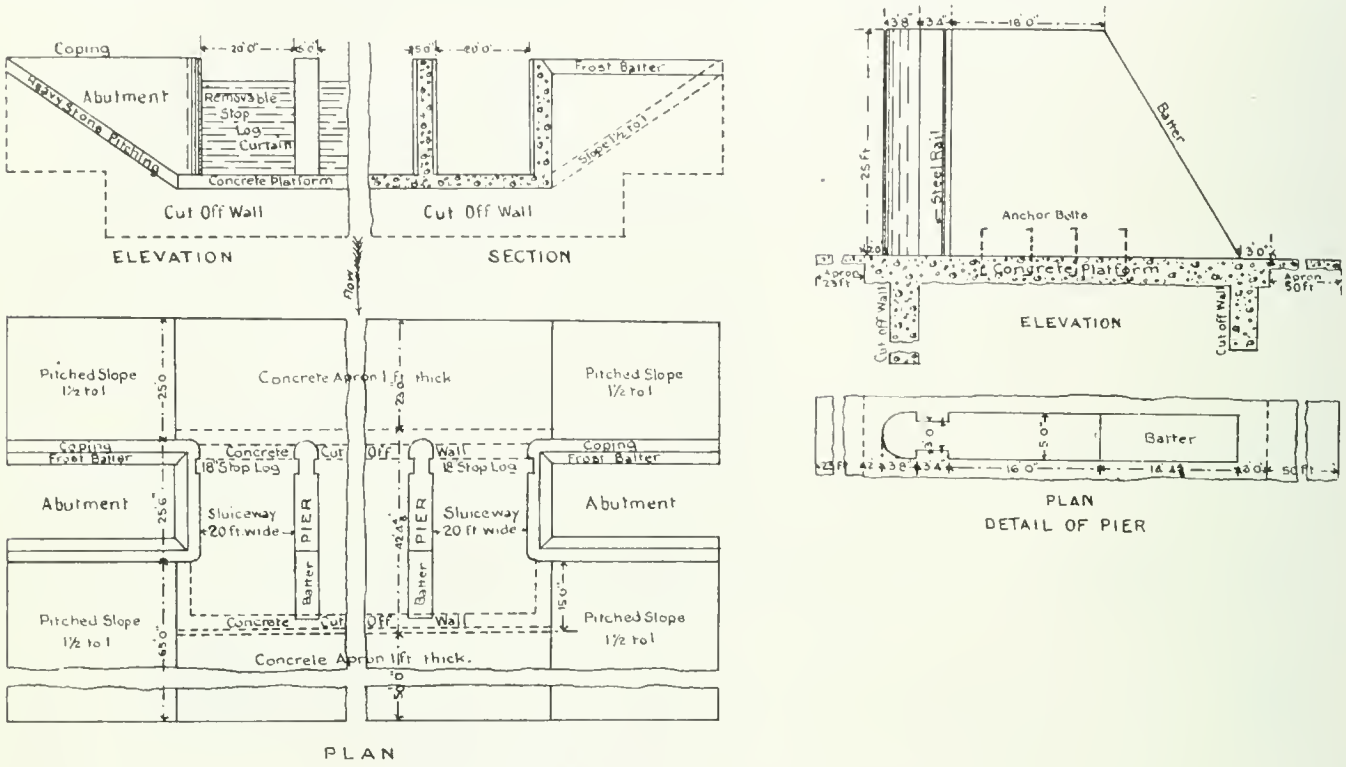

Fig. 3.—General Plan of Concrete Sluiceways.

For general information it may be observed that each crib is a crate formed of 10- to 12-inch timber built in courses "log cabin" fashion. In this case the cribs or boxes were 20 to 35 feet in the direction of the current and 18 to 30 feet long, the depth averaging 20.5 feet. Each crib had cross ties between the up- and downstream faces, at 6-foot intervals in each course and longitudinal to provide rigidity, leaving a series of pockets into which the stone filling was loaded.

To set the individual cribs in place, in a rushing current 20 feet deep, was a difficult matter, and for this purpose an anchor crib was built and sunk above the line of cofferdam. Each crib was built on shore to a height of about 12 feet, then launched, attached to the anchor crib with a 1¼-inch wire cable, and gradually lowered downstream to the line of cofferdam. By side lines of wire cable leading to the island and the Quebec shore, the crib was brought to its place. As the channel was narrowed by placing cribs in this fashion, the velocity of the current increased. This condition was provided for by a heavy wire rope tackle attached to the end of the 1¼-inch cable and passed around the drum of the alligator's winding engine. The power thus secured was ample, the alligator being well anchored, and cribs could be set within an inch of their proper line.

fill in afterwards as occasion allowed. In like manner several of the piers were built before the east end of the platform had been laid, but no difficulty was found in making good junctions.

Fig. 4.—Ontario Sluiceways, Timiskaming Dam, Showing Swiftly Flowing Approach Current.

At first the whole structure, abutments and piers were built only to elevation 583, or 10 ft. below final height. This was high enough to withstand flood water and in case of an early rise it was thought best to bring everything to a safe height. Time, however, allowed the finishing of the whole structure to full height by the end of April. Since then the bridge across the sluices has

been completed and the work is now being put into a neat and finished condition.

Work on this dam began in the spring of 1909, and was continued by the Canadian Government until its completion this year. The construction of the dam was under the direction of Mr. C. R. Coutlee, engineer-in-charge, and he directly under Mr. A. St. Laurent, Assistant Deputy Minister of Public Works. The above information is largely from a recently issued report to the Minister of Public Works.

PRODUCTION OF MALLEABLE CASTINGS.

MR. RICHARD MOLDENKE has extracted from an address given before the Connecticut Valley Section of the American Chemical Society, Hartford, Conn., the following section, and has published it as an article on the production of malleable castings, considering particularly the special uses of the several melting methods, systems of work, composition of the product, and annealing.

"Malleable making processes are the crucible, cupola, Bessemer converter, air-furnace, open-hearth, and electric. The crucible process makes the finest malleable as it does the finest steel, with the exception of the electric furnace. You find the crucible made casting only in Europe where the malleable is more expensive than the steel casting.

"The cupola is for such castings as pipe-fittings, agricultural work, and those things that require only a little better strength than the gray casing of the same kind, but more malleability. Cupola malleable is a little cheaper than the air-furnace or open-hearth product. In all malleable melting processes, inasmuch as the iron is low in silicon and consequently sets quickly, it loses its life easily; and especially if it has been oxidized at all it must be gotten into the mold fast. Consequently a gray iron molder must be shown how to pour malleable; a little twist of the wrist throws the iron into the mold; otherwise it may be short poured. In cupola melting there is always a very low coke ratio; melting is done on a high bed; perhaps higher than it ought to be, but it is necessary to get the iron very hot and as free from oxidization as possible.

"The Bessemer process is used only in Europe. They blow their heats to where the silicon is down to the right point, stop the heat, dioxidize and pour. With the long anneal, in which the metal is decarbonized, they should make serviceable castings.

"The air-furnace is principally used for "malleable" in this country. Malleable air-furnaces are constructed differently than are air-furnaces for gray iron work. For gray iron they have large cross-sections and are comparatively short. For malleable very long furnaces are used, a long flame being desired. The heat to melt, whether in air-furnace or open-hearth, does not come from the direct action of the flame so much as it does from the radiation of the interior brickwork. The idea in the air-furnace and in the open-hearth furnace is to get the brickwork lining so hot that the radiation downward upon the charge does the actual melting, and does it fast. I have seen a pound of coal used for melting every pound of iron, whereas it ought to be about four pounds of iron to the pound of coal when you run three heats in one day and average them all up. The first heat with the colder furnace is a little harder on the coal supply than the others.

"Not unusually you will find that you can look through the brickwork into the interior, there being plenty of spaces where cold air is drawn in. The radiation of the lining does the business and every square inch of the interior of the furnace should do its work.

"I have seen men throw coal all over the bed of fire and then take the slicebar and poke it up, whereas the right way to do is to pile the coal at the door, shut the door, allow this coal to coke slightly, and then carefully push it over the entire area. Then repeat the operation, and repeat periodically instead of having the fireman using his shovel and bar all the time.

"If we get more than 25 per cent. excess free air in the malleable furnace we begin to get trouble. If that 25 per cent. in excess can be allowed uniformly, we get that magnificent incandescence which does the melting properly.

"Starting with, say, 0.95 silicon in the mixture if the heat is made sharp and short this silicon content will be lowered to the 0.65 required for the ordinary run of castings nicely, and it will drop from 0.65 to 0.60 from the beginning to the end of tapping, whereas with a long, slow melting the iron may be 0.65 at the beginning of tapping and down to 0.55 at the end of the heat or a loss of twice the silicon. When this occurs the iron has begun to oxidize. Another thing: Take a bath of iron in the air-furnace which is deep near the bridge, and feathers out to nothing at the stack. If there is any one thing dangerous in the air-furnace it is that thin, feather edge at the end; because there all the gases are swept over it, and the heat is transmitted into a very thin body of metal. Consequently, the temperature rises very fast at that spot; and the iron is liable to burn.

"The open-hearth furnace is the best melting process except the obsolete crucible and the electric. The open-hearth furnace melting process is applicable only where there is enough work to keep the furnace running steady. Melting ratios are: cupola, 1 to 8; air-furnace, 1 to 4; open-hearth furnace, 1 to 6. Air in the open-hearth furnace has about 1,000 degrees F. heat. A good heat of 10 tons in the air-furnace may take four hours, but we can run the same heat in two and a half hours in the open-hearth (from end of charging to beginning of tapping).

"In making malleable you have a great big bath of molten iron, hot on top, and cooler on the bottom. Test plugs show crystalline and white fractures; the composition is right. You draw the colder iron from the bottom first. Top of charge comes down maybe an hour later. In the meantime the oxidizing reaction goes on; the slag has been taken off; there is a direct contact with the gases, the metal is damaged. It should really be taken from the top first. The ideal method of getting iron out of an air-furnace is to take it from the top. The tilting furnace gives this result. I patented a three-spout arrangement for my furnaces, thus taking off six or seven tons from the top; then the next six or seven tons below; then break the breast out and get the rest of it from the bottom. In my open-hearth practice I never skim, but let the slag cover the iron.

"The composition of a malleable casting, so far as the silicon is concerned, depends on its thickness entirely. In ordinary work the silicon should be about 0.65. For very heavy work I used to turn my silicon down to 0.45. In the old days of charcoal iron my regular silicon was 0.35 (charcoal iron could be used as low in silicon as 0.10). With coke irons it is not wise to have pig iron with less than 0.75 silicon in stock. In making cold-blast

charcoal iron you have a very small furnace to begin with; charcoal which eagerly absorbs oxygen as a fuel and hence the iron sponge formed melts with the least chance of oxidation. With the hot and more powerful blast, there is a little further penetration of free oxygen; with the consequent greater oxidation of the iron sponge as it melts, and hence a weaker iron. With coke fuel there is a very serious entrance of free oxygen. Coke does not unite with the oxygen in burning as fast as in the case with the charcoal. The difference between charcoal and coke irons lies only in this oxidation question.

"In annealing, the idea is to get the castings up to the annealing heat quick, hold them at annealing heat for a given time—60 hours is best—then to let them cool gradually. Pack the castings in oxide of iron. We use puddle scale, a silicate and oxide of iron, the flakes from the pots. They are almost pure iron oxide. In some railroad work, as tie-plates, these can be put loose in the oven, practically make a retort of it and use no packing whatever. The castings look rough but are good enough for the purpose.

"As to temperature of the anneal—the old-fashioned way of looking at the cracks in the brickwork to see the white line is very good if the eye of a man does not change. I prefer the LeChatelier pyrometer. Temperature at the coldest point of the coldest pot should be 1,350 degrees F.; it may go as low as 1,250 or it may be as high as 1,400. For cupola iron, the temperature must be about 200 degrees higher, because the iron was melted in contact with the fuel, and has a higher sulphur content, which obstructs the annealing changes at lower temperatures."

NEW POWER STATION AT KAMLOOPS.

The opening of the Kamloops, B.C., power station took place on October 28th. This station will be a component part of the extensive hydro-electric system, the total cost of which will amount to about half a million dollars, and which will give Kamloops all the additional power needed for many years. Work is now well under way at the Barriere River, 40 miles north of the city, where if necessary some 10,000 h.p. is capable of development. Some 2,000 h.p. is now being arranged for. This, along with present power, will run all the municipal industries and many more which may be established here in the future. The new power station is a reinforced concrete building, 80 by 90 feet in size.

The largest railway station in Europe, estimated to cost $35,000,000, is now under construction at Leipzig.

The Chino-French Bank has signed a contract for a loan to the Chinese Government of $30.000,000. Of this sum $12,000,000 is intended for the construction of the port of Pu-Kow, in the Province of Kiang-Su, and $12,000,000 for the building of a bridge between Hankow and Wu-Chang, over the Yank Tse River. The remainder, $6,000,000, goes to the Chinese Minister of Finance.

The new Gladstone Dock at Liverpool is 1,020 feet long, 120 feet wide, at the entrance, and carries a depth of water over the sills of 46 feet at high water of ordinary spring tides. This dock is the first instalment of a scheme involving the expenditure of $16,000,000. The proposed work includes also an entrance lock over 870 feet in length and 130 feet in width, and in the inside dock area there is to be a half-tide dock of 14¾ acres, two branch docks, each 400 feet wide, with a pier between them over 1,300 feet in length.

AUTOMATIC RAILWAYS.

By Reginald Trautschold, M.E.,
Consulting Engineer. New York City.

THE material-handling apparatus so far considered in these articles have all called for a supply of power from some outside source for performing their operations of conveying or elevating, or both, and their respective true economic value is largely a question of economy in consumption of power. In fact, their economic value might almost be said to depend upon their mechanical efficiency, the proportion of the total amount of power supplied converted into useful work—work actually performed; total energy supplied. There is one variety of equipment of the intermittent type for conveying, however, that performs such operation without necessitating the supply of any power and would thus appear to have an incalculable economic value. This is not quite true, for this peculiarly efficient system requires the performing of considerable preliminary work, the net mechanical efficiency of the material-handling system then necessitating the consideration of all work done, the preliminary work as well as the work that required no supply of power. However, the "automatic railway," the system referred to, is of particular interest and of very high economic value in many undertakings.

The automatic railway is based on the principle that the momentum of a body descending an inclined plane, like a falling body, is dependent upon the velocity at which it travels and the weight of the descending body and that if the energy required for bringing such a moving body to rest should be applied to another lighter body, or the same body after it has been lightened, it would cause the second body to rise until the energy consumed by such operation equalled that required to bring the first heavier body to a state of rest. Theoretically, the horizontal distance over which such automatic operation could be performed would be unlimited but the necessity of limiting the maximum speed of the descending body, the practical limit to the momentum that can be overcome and partially returned to the lightened body, etc., places a limitation of 600 feet for the operation of an automatic railway. Practical application of the principle calls for a car of special design for the conveyence of the load; a weight, attached to a cable, for operating the system; and a cross-bar, also attached to the cable, which is picked up by the descending car, as it approaches its discharging point, gradually raising the weight until the car stops—the car automatically dropping its load between the time that the loaded car picks up the cable and the time when the raised weight overcomes the momentum of the moving car. The weight, falling from its elevated position, then pushes the lightened car back along the track towards the loading point with sufficient force to return it to the starting point, there to be reloaded and the cycle repeated.

Ordinarily the inclination of the track for such operation is that which causes the car to attain a mean speed of 600 or 750 ft. per minute between loading and discharge points. Such speed is, of course, subject to considerable variation, as on a short railway the inclination of the track necessary for attaining such a mean speed would be excessive and in runs approaching 600 ft. in length, the mean speed attained by the car is frequently greater than 750 ft. per minute. The weight for arresting the travel of the car and to give the requisite shove to the returning car should advisably perform the first

operation gradually—that is, the resistance to the further forward travel of the car should advisably commence at a minimum and increase gradually to a maximum as the travel of the car grows slower—otherwise the shock of the car at its maximum speed with the cross-bar, which transmits the shock to the operating weight through the medium of the cable, would be too great for most satisfactory operation. The second operation, that of giving the emptied car sufficient shove to send it back to the loading point, requires application of power in somewhat different order. First, sufficient force should be applied to start the car quickly on its return journey and to enable the car to pick up its maximum return speed as rapidly as possible, after which sufficient force to overcome the resistance to the return travel of the car is all that is required, though it is advantageous to have force acting against the car—in the direction of its return travel—for as long as is feasible. The requirements for both these operations are closely attained by a weight so attached to a rigid support on one side and the operating cable on the other that, when not in use, the weight lies between and is balanced by the tension in the idle operating cable on one side and the rigid support on the other. The cable, picked up by a descending car, raises the weight which, on account of its pivoted attachment to the rigid support, swings about the arc of a circle, causing the pull on the weight to become gradually less effective as far as lifting power is concerned and thus gradually increasing the effective pull of the weight on the cable while, at the same time, the momentum of the descending car is greatly reduced by the discharge of the car load. On the descent of the weight to its position of rest, the pull of the weight on the cable is at a maximum at once and maintains powerful until the car picks up its speed, the speed of both car and cable increasing during this time from zero to that of top speed of returning car. Further descent of the weight tends to cause its fall to grow more rapid and the pull-in of the cable to become more rapid still, the effective pull of the weight on the cable meanwhile becoming less. The empty car having attained its maximum speed, then retards the acceleration of the pull-in of the cable thereby reducing somewhat the shock of impact of the weight on coming to rest—the shock in the cable caused by the completion of the fall of the weight. Any stretch in the operating cable is likewise neutralized, the only rigid connection of the cable being at the far end of the track so that a lengthened cable simply means a little further fall of the weight.

The car generally used on an automatic railway is of the double side dump type, of either one or two-ton capacity, and the automatic tripping device for actuating the release of the car sides is located at the side of the track between the point where the car picks up the "cross-bar" and the end of its travel. The "pick-up irons" for engaging and carrying forward the "cross-bar" are attached to the front of the car and the "cross-bar" is rigidly attached to the operating cable so that the forward travel of the "cross-bar" raises the operating weight until the momentum of the moving car is overcome. The "cross-bar" also gives the empty car the necessary shove for its return trip. The standard type of automatic railway car is built with a gable bottom, with sufficient pitch for rapid drop of load, so proportioned as to throw the load clear of the rails—the standard track gauge being 21 in., 0 to 0.,—and with the car wheels clear of the body proper. This arrangement permits the construction of a low car, presenting comparatively small surface to air resistance, with a wheel base that is not unduly long—in fact, the standard automatic railway car has a wheel base sufficiently short to enable it to take a curve of 30 ft. radius. Such curved sections of track must be confined to sections near the loading end of the railway, however, discharge of load requiring straight track, the operating cable having to be straight and free beyond the cross-bar.

The capacity of an automatic railway, though necessarily rather low when compared to that of a system for continuance conveyance or of one that permits the use of the car on its return trip, compares quite favorably with car-hauls and similar systems that also usually carry their load but one way—the mean speed of car travel being high and little time wasted in loading if the car is filled directly from an overhead hopper of adequate capacity. The car is usually comparatively small so that an expert operator is required to obtain a carrying capacity of 50 tons per hour on a railway 300 ft. long with a 1-ton car or of 90 tons per hour with a 2-ton car. Under the same conditions of service, doubling the length of the railway

would not cut the carrying capacity in two nor would the difference in capacity between similar railways with 1- and 2-ton cars be so marked, about 38 tons per hour being obtainable with the smaller car and 65 tons per hour on the long railway with a 2-ton car. Such capacities require the handling of material weighing from 50 to 60 pounds per cubic foot and efficient loading of the car from an overhead hopper of adequate capacity and free discharge.

To arrive at the net cost of operation of an automatic railway requires consideration of each individual installation as so many conditions must be known that no law can be advanced for even approximate calculations. For

instance, in the case of four similar railways; two of 300 ft. and two of 600 ft. length, one 300-ft. railway equipped with a 1-ton and the other with a 2-ton car, the 600-ft. systems similarly equipped; all handling material of such weight as to carry their rated capacity on each trip and all so efficiently loaded as to be able to realize about the highest hourly capacity of each installation, the cost of labor chargeable to each ton carried would vary considerably, for but one good operator would be necessary in any case. The cost of operation per ton handled on the longer of the two systems with 1-ton cars would be but 30 per cent. more, as far as labor or attendance is concerned, than on the shorter railway, while similar comparison between the two 2-ton car systems would show a labor burden of 36 per cent. more for the longer than for the shorter system. A comparison of the two 300-ft. systems and the two 600-ft. would show an increased burden for labor per ton for the shorter installations of about 80 per cent. for the 1-ton car railway, and for the longer installations of about 70 per cent. more for the railway with the small car.

Installations of the same length and similar cost of construction would vary somewhat as to first cost, depending upon whether equipped with 1- or 2-ton cars and similar installations, as far as construction cost and size of car, but of different length, would also vary, it is true, but this variation would scarcely effect the economic value of the installation, as the burden imposed by interest on investment, taxes and insurance would be the only items to appreciably affect the net cost of operation. These items would in themselves not vary to any great extent, for initial cost of installation would not differ much between a 1-ton car or a 2-ton car railway, nor would the cost of similar installations of different length vary directly with the length of the railway; rather the cost per foot of railway would vary more nearly inversely as the hourly capacities of the systems. For instance, the cost per foot of a 300-ft. railway would average about 30 per cent. more than the unit cost of a similar railway 600 ft. long. The customarily necessary allowance to make for depreciation, renewals, etc., can almost be neglected in the ordinary automatic railway installation, as there are many instances on record where such systems have been in almost continuous daily operation for over 40 years with practically no depreciation evident, the originally installed car still being used, and no renewals except a very occasional new cable or possibly a new sheave or block.

The variable labor charge may also be greatly discounted, for, in the average installation, some attendance would very probably be required at the loading hopper if the operator of the railway was not present. The cost of elevating the material handled to the loading hopper or to the automatic railway car itself—installations occasionally being made where the car is loaded directly from the apparatus performing the preliminary work of elevating the material to be carried—is rarely more than would be required for similar operation by any other system that could be employed to handle the load to the point where the automatic railway car drops its load to bin or storage, not more than a few additional feet of elevating being required for the material to be discharged to a loading hopper of even the largest size ordinarily employed.

In operations requiring the knowledge of the exact weight of material handled, the automatic railway enables such records to be kept easily and economically, without the necessity of any delicate or complicated automatic weighing devices, etc. A platform car scale with double beam is the only accessory necessary. The operator simply records the weight of the empty car on one beam, then loads the car and balances the weight of the loaded car on the second beam, the reading on the second beam then gives directly the net weight of the load, which may be entered in a "tally book" while the car is traveling from the loading hopper to the discharge point and back. This semi-automatic weighing system accurately measures the exact amount of material that is discharged from the car, any material remaining in the car being accounted for in the next empty car reading and subtracted from the load dropped by the car on its next trip.

Possibly the greatest advantage of the automatic railway, however, is the reliance that may be placed on its continual operation. Once properly installed and adjusted, no attention at all is required other than an occasional inspection of cable, etc.—the car always automatically returns to the loading point after discharge of load, so is always ready for operation. High-grade ball or roller bearings are used for all rotating parts so lubrication is reduced to a minimum and the general high-grade of equipment that the system required for satisfactory operation minimizes the expense for incidental supplies of all kinds.

The disadvantages of the system are exceedingly few, one being its somewhat limited capacity. This, however, is no great detraction, for, requiring no supply of power for its operation, it costs practically nothing to have the system in operation for sufficient time to enable it to carry all the material that a power-consuming conveying system of greater hourly capacity could handle in considerably less time but with a charge for power, increased burden of depreciation, etc., and probably a heavier attendence charge for the shorter operative hours than that entailed in caring for the slower system. Another drawback to the automatic railway is its comparatively short operating range. This is limited to 600 ft. as the maximum, and it is doubtful whether railways shorter than 50 ft. in length would operate entirely satisfactorily owing to the comparatively short distance that the descending car would have in which to store up momentum sufficient for the operation of the system. However, this limitation does not affect many installations where the mechanical handling of materials is advisable if not necessary.

Although the automatic railway is primarily designed and adopted for the handling of material in bulk, which can be automatically dumped from a gable-bottomed car, modifications of this standard have been installed for handling materials in bags, etc. For such service, a special type of flat car is used equipped with a mechanism by which the car is held stationary on completing its forward travel, at the unloading point, the operating weight of the system being held in an elevated position at the same time. On unloading the flat car, the holding attachment is released and the operating weight of the system drops and pushes the unloaded car back to the loading point.

[NOTE—This article is the seventh of a series on "The Mechanical Handling of Materials," written for *The Canadian Engineer* by Mr. Trautschold.—Ed.]

Boston proposes to have a forty-foot channel in its harbor because there is now in commission and in prospect ships requiring that depth of water. Boston now has in its service mammoth liners drawing from 32 to 33½ feet. In July this port handled twice as many ocean passengers as Philadelphia, and four and one-half times as many as Baltimore.

THE ROTARY TYPE AIR PUMP.

During the past few years, there has been an increasing demand for rotary air pumps for use in connection with surface condensers in steam turbine plants. Such a system seems to have several advantages, chief among which is the factor of space efficiency, as well as general simplicity and absence of reciprocating parts.

The illustrations shown herewith relate to the Willans rotary air pump system, a product of Willans and Robinson, Limited, Rugby, England. This system is brought out under license for the Müller-Josse Patent, controlling a system extensively used on the continent in condensing plant construction in sizes ranging as high as 10,000 K.W. Fig. 1 shows a diagrammatic sketch of the two most common applications of this system, viz., the shunt and the series system. In either case, the air is extracted from the condenser by means of the air-ejector, and the condensed steam is withdrawn by a separate centrifugal pump drawing the water from the bottom of the condenser. The piping for this operation for both systems is well illustrated in Fig. 1. The two systems differ in the manner of supplying the water to the air-ejector. The shunt system is used where the head across the circulating pump, as given by the local conditions and the pipe and condenser friction, suffices for the purpose of extracting air. In such case, the main circulating pump is designed to deliver a greater quantity of water than is required as cooling water in the condenser, the surplus water being used as air-ejector water, and returned to the source of supply or to the suction side of the circulating pump.

Where the series system is used, the whole body of the condenser cooling water is passed through the air-ejector before entering the condenser. Thus, in the shunt system, the power required for extracting the air is determined by the surplus quantity of water at the given head, and in the series system by the given quantity of water at a surplus head. In neither case is a greater quantity of cooling water consumed than where a reciprocating air pump or any other rotary air pump is used. Only one simple centrifugal pump is needed for supplying the condenser cooling water and the air extraction water.

The power required in extracting the air is dependent on the design of the ejector and the power actually consumed in compressing the air. The ejector used is the outcome of exhaustive experiments, and is said to be equal at least to any other form of ejector, either stationary or rotary. To reduce to a minimum the power required in air compression, the line of compression should approach the isothermal as closely as possible and compression should be carried out at the lowest possible temperature, namely, the temperature of the cooling water. Generally speaking, other rotary air pump systems call for special water tanks for holding the water required for air extraction; moreover, this water heats up rapidly owing to the small quantity of water in the closed circuit, and provision requires to be made to change the water frequently. Even so, the temperature of the water cannot be maintained at the temperature of the circulating water supply, and consequently the power consumed in compressing the air might be expected to be somewhat less in the system under description. Exhaustive tests have shown that in power consumption a very high efficiency has been obtained by this system, higher, it is claimed than for any other air extraction system dispensing with reciprocating pumps.

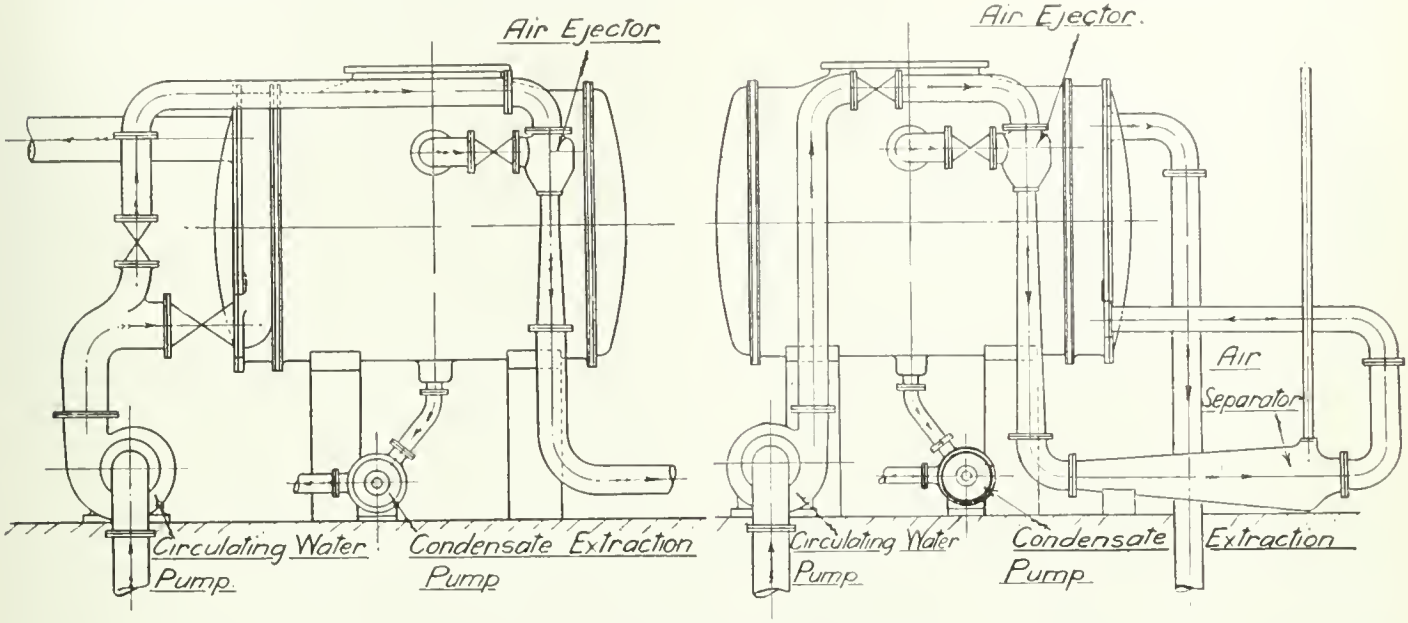

Fig. 1.—Shunt and Series Systems.

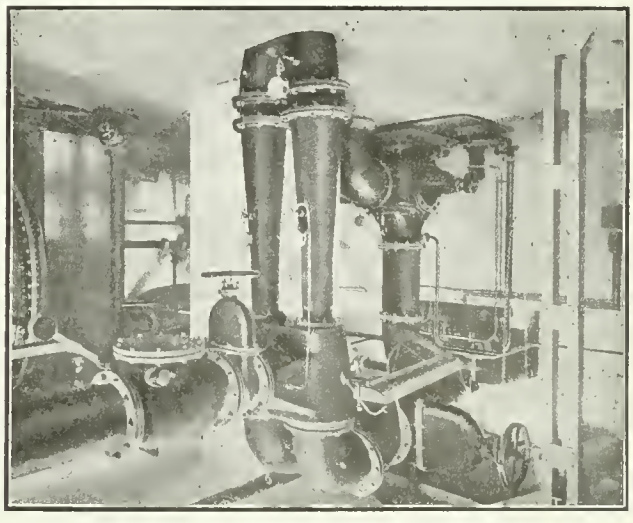

Fig. 2.—A 4,000-kw. Installation.

Fig. 2 shows a 4,000-K.W. surface condensing pump in operation. It might be stated that a total of 150,000 K.W. output measures the capacity of turbines for which condensing plants of this type have been built or are building.

COAST TO COAST.

Winnipeg, Man.—The first 25-mile stretch of the Winnipeg-Winnipeg Beach highway has been formally opened. The ceremony took the form of a luncheon, tendered by the municipalities interested, to Premier Roblin, Sir Rodmond and the Hon. Dr. Montague, minister of public works, and others taking a prominent interest in the construction.

Regina, Sask.—A report has been submitted to the street railway committee of the Regina city council covering the operation of the municipal street railway of the city for the eight months ending August 30th. This shows that after providing for operating expenses and capital charges there is a deficit of $31,872.34.

Vernon, B.C.—A great asset for tourist and travelling parties visiting the Okanagan Valley has been furnished by the completion recently of one and one-half miles of macadam road to connect Kelowna and Vernon. This road, which forms a contour highway, cut into the hillside above Kalamalka Lake, has been opened to traffic by a public ceremony conducted by those mainly by whose efforts it has been constructed, e.g., Hon. Price Ellison, Mr. G. A. Henderson, manager of the Bank of Montreal; Mr. Hamilton Lang, superintendent of roads, and his assistant, Mr. G. M. Watt.

Vancouver, B.C.—Discussing the progress of the work along the Kettle Valley line, Mr. J. J. Warren, president of the K.V.R., said of the 295 miles of track to be laid between Midway and Hope that steel had been installed for more than 100 miles and almost 200 miles of grading had been completed. In addition to the track laid through the Boundary, Kootenay, Kettle Valley and Okanagan districts, 25 miles of line have been finished from Merritt to Coldwater Junction. Machine shops and roundhouses have been established at Penticton and good progress is being made all along the route.

London, Ont.—During the year 1913, London's engineering department has expended $214,705.08 on local improvements; and up to date this is a record amount. This year is also on record as showing the inauguration of the municipal contract system, which has proven to be eminently satisfactory. Of the total expenditure, $5,500, or approximately 2½ per cent., covers the salaries for the engineering department and office expenses for the eight months of outside work. This is an entirely significant feature, since a 5 per cent. basis is considered low for engineering supervision and plans.

Owen Sound, Ont.—The great loss of life and wreckage of vessels on the Great Lakes has been attributed largely to the fact that national elevators are erected at harbors of the most difficult approach and of the least adequate protection. It is therefore being agitated among leading citizens of Owen Sound, that the Government be approached with a request to construct at Owen Sound, where the harbor offers the easiest and safest ingress of any on the Great Lakes, a national elevator or elevators; and already representations have been made in connection with the matter to the proper departments at Ottawa.

Victoria, B.C.—It is expected that the steel bridge which has been in course of construction over the Little Qualicom River will be completed in a few days. This is on the Courtenay extension of the line, and, when finished, the laying of the steel will be proceeded with as far as Big Qualicom. While this work is under way the bridge gang will be transferred to Cowichan Lake to erect a steel bridge for which the foundations have been finished. This done the outfit will be removed again to Big Qualicom, which project will be carried forward as rapidly as circumstances permit. It is believed that the East Coast extension will be opened for passenger traffic by July 1 of next year.

Regina, Sask.—The development of the Saskatchewan Co-Operative Elevator Company during its short lifetime was reviewed at the recent annual meeting held at Regina. The first year the company operated 46 elevators, with 2,590 subscribers, and handled three and a quarter million bushels of grain. During the second season's business, which ended July 31, 1913, the company operated 137 elevators, with 8,962 shareholders supporting them, and thirteen million bushels of grain were handled. This year the company has 193 elevators, the total number of shareholders being 13,000; and up to September 20th, the company has handled considerably over 1,000,000 bushels of this year's crop.

Hull, Que.—The committees from Hull and Ottawa, appointed to arrive at the basis of an agreement between the two cities for the right-of-way of the Gatineau Lakes pipe line through Hull, have found only one difficulty in the way of a satisfactory agreement, e.g., the price which Hull shall pay for the privilege of taking water from the Gatineau system. In the proposed agreement Hull asks for a rate of one-quarter of a cent per 1,000 gallons, which is the rate that that city is paying at present. In return for this rate Hull will grant the right-of-way free of charge, and also an exemption of taxation until such time as the city of Hull decides to take its water from the new system.

Montreal, Que.—The City Council inspected recently the work on the filtration plant which is proceeding under the direction of Mr. Norman M. McLeod. The controllers found that a great deal of progress has been made. To obviate the damage by frost, which wrought such havoc with the plant last winter, the filtration plant is being put under four or five feet of water for the winter. The contractor has been helped forward on the work by the particularly favorable nature of the weather this autumn. The council was particularly satisfied with the enlargement of the aqueduct and the laying out of the twin boulevards on either side of the waterworks canal, the work on which is being done by the Cook Construction Company.

Montreal, Que.—Improvements upon the city's original sewage farm have been completed at a cost of about $120,000. These improvements were necessary before the farm could be used for the purification of the matter flowing from the sewers to the river. The new farm, purchased a year ago, is to be improved next year at a cost in excess of that of the work on the first farm. It is estimated that the total cost of the enire sewage farm when completed will be between $395,000 and $400,000. The work carried out during the past year on the old farm has been the adding of stone to the property so as to produce an effective filter for the sewage, the land having proven itself not sufficiently porous. The same method of treatment is to be given the new farm, and the final result will be that, in the course of twelve months, all the city sewage will pass through this farm and be purified before emptying into the river. Thus, contamination of the water supply will be obviated.

Toronto, Ont.—At the last meeting of York County Council, Mr. E. A. James presented an interim report on behalf of the Highways Commission of York county; and a complete report is to be forwarded to the council before the end of the year. Mr. James' report shows a total expenditure on construction of roads and bridges during the year of about $60,000; and on maintenance, of $14,000. Owing to the request of the Government that no extensive work be undertaken pending the report of the Provincial Highways Commission, construction work was restricted to completing

gaps between sections already built. Some of the most important work was one mile of macadam construction on Yonge Street at Thornhill; 1,500 feet of brick pavement on Weston Road west of Black Creek; and three-quarters of a mile of macadam roadway in Vaughan township. Other road construction was 8,470 feet on Kingston Road, 8,500 feet on Vaughan Road, and 6,700 feet on Markham Road. On bridges and culverts the total expenditure, including construction and maintenance, for the year was $16,342.

Vancouver, B.C.—The final consignment of steel pipe contracted for by the city at the beginning of the year has arrived from the Mannesmann Tube Company of Great Britain; and the city has now on hand between 80 and 90 miles of water pipe. Only about 5½ miles of mains have been laid from this year's pipe; and it is estimated that the city will have a supply on hand to last for several years. When contracts were let to the National Tube Company of Pittsburg for 320,000 feet and to the Mannesmann Tube Company for 110,000 feet, it was intended that the pipe should arrive at periods, considerably apart; and it was thought to thus obviate the difficulty met with in the past owing to non-arrival of the pipe in time. As the case now stands, and owing to the serious drop in the demand for mains, it is asserted that the pipe will rust long before the city can use it. Last year, the city engineer's report showed that 47.8 miles of pipe of all sizes had been laid; but this year only about 17 miles of water mains have been laid. This is due largely to the falling off in building operations this year in Vancouver.

Victoria, B.C.—According to Mr. D'Arcy Tate, vice-president and general manager of the P.G.E. railway, the company will complete its contracts within scheduled time in spite of unforeseen engineering difficulties encountered on the northern section of the line. The section between Point Atkinson and Newport promises to be one of the most costly pieces of construction on the entire line, and will involve an outlay of about $100,000 a mile. This will mean practically the laying of the road on a bed of solid rock. In the Upper Fraser country there will be big rock fills; but the nature of the sub-structure is such that this part of the line will be built for less than one-half the cost of the Newport section. A short section of the line between Newport and Cheakamus, about seventeen miles in length, will be completed this week, and it is probable that Sir Richard McBride will open this small length and at the same time take the opportunity of making a personal inspection of the progress made in construction. The North Shore section will be ready for traffic by January 1 of next year, and the next section by the end of the following July, in accordance with the terms of the contract.

Niagara Falls, Ont.—Mr. Frederick Walker of New York, has devised a plan to build a suspended raceway at a cost of about $2,500,000, to tap one-half of the waterfall from the Canadian Falls and one-half from the American Falls at Niagara, and to carry the water through the Niagara River to a point where a great power plant will be erected for the creation and distribution of electricity. The power plant, which is not included in the estimate of cost, would furnish unlimited power to factories in Eastern Canada, just as the Niagara Falls Power Company's plant furnishes power to factories in Western New York and Pennsylvania. The plans provide for the raceway to be suspended with one end upon the rocky ledges of the Niagara River and the other planted on the river bank, and to be arranged so that if the river rises or falls, the raceway will rise or fall automatically. The raceway will follow the Canadian shore for several hundred rods before reaching the place where the power will be harnessed; and its carrying capacity will be about 1,200 pounds to the foot. It will be constructed of steel and concrete. Already surveys for the work are being made, under Mr. Walker's supervision; and options on land on the Canadian side are being received by other men interested.

Montreal, Que.—Col. Greenwood, assistant chief engineer of construction on the C.N.R. east of Port Arthur, has inspected the bridges under construction for the company at Back River, and reports that Mr. J. P. Mullarky, the contractor, is rushing the laying of track on the section from the western portal of the tunnel to the crossing of the Back River so that the steel superstructure may be brought for the series of bridges across the Riviere des Prairies and Mille Isle. There are two channels at the Back River, each being crossed by 4-pier bridges. The middle pier of the first channel bridge alone remains to be finished; and for this the coffer dam is now being sunk. On the second channel bridge all the substructure has been placed in position. Where the C.N.R. crosses the Mille Isle, there is being built a bridge of 14 piers, all of which are completed. This is one of the most imposing structures on the main line of the railway; and the superstructure for it will be placed during the coming winter. All other bridges along the road as far as Carillon have been completed, while the sub-structure of the big bridge over the Ottawa River at Portage du Fort, a structure of 12 piers, has also been finished. The C.N.R. main line runs up on the Ontario side of the Ottawa River for a distance of 30 miles as far as Shaw Falls, and then crosses into Quebec. After continuing for 30 miles in Quebec territory, the line crosses the river into Ontario again by the Portage du Fort bridge.

Montreal, Que.—Much is planned to be effected at the Montreal harbor before it is opened again in the spring. Before that time the slope of mud and clay at the river edge of Victoria, the dingy old dredge, and the clamshell derrick will all have disappeared; and a smooth concrete wall, of a height uniform with the other high level wharves of the upper harbor, and another of the huge freight sheds which line the wharves all the way to Windmill Point, will have appeared. Half a mile down the shore, from sections 24 to 27, where new concrete piers lying parallel with the river have been constructed during the summer, two more big freight sheds will have appeared. The piles for these have already been driven—long, concrete stilts, thrust down to the rock to take the strain off the heavy structures with the thousands of tons of freight, which they contain when in use. New berths at Victoria pier will be ready to give every opportunity for loading grain. Above the roof of the new freight shed the conveyor gallery will be extended to the very edge of the river. This will be the last link in Montreal's wonderful elevator chain. It will make one continuous system from Victoria pier to the western end of the Allan Line shed at the foot of McGill street, which in all will then have close to 16 miles of belt conveyors to carry the grain from unloading tower to elevator, or from one elevator to another; or, finally from either elevator to any ship lying anywhere between those two extremes. Four miles lower still, a like transformation will have taken place at the site of the Canadian Vickers Company's shipbuilding and repair plant. Acres of mud and construction materials will have vanished and a concrete retaining wall, which will make the whole water frontage of this tract one big wharf, and a heretofore much-needed machine shop of immense proportions, will have been completed. Further improvements that will add materially to the rejuvenation of the harbor, will be the Armstrong steel plant directly across the river; and the river bed itself, which will have a newly dredged channel for the use of light craft in general, which will wind along on the north side of the deep channel, the passageway for large vessels.

PERSONAL.

A. K. GRIMMER, City Engineer of Medicine Hat, is at present on an extended trip through eastern Canada.

GEORGE T. CLARK, City Engineer of Saskatoon, Sask., has, it is announced, placed his resignation, to take effect February 1st, in the hands of the city council.

M. R. SHAW, B.A.Sc., is assistant superintendent for the Muskogee Refining Company, refiners of illuminating and lubricating oils and paraffine, Muskogee, Okla.

W. E. SKINNER, of Winnipeg, has been retained as consulting engineer for the town of Kenora, and will make a report upon the cost of producing power at the municipality's hydro-electric plant.

P. P. VON WEYMORN, civil engineer of the water power department of the Russian Government, is at present in Canada, to investigate the regulations of water power now in force in this country and the system of administration. For the past month Mr. Von Weymorn has been carrying on an investigation in the various cities of the United States, and is now visiting Canadian cities. He is very much impressed with the results of his investigations so far, and thinks that the regulations of water power of the Dominion Government are the best he has seen so far.

OBITUARY.

The death was recently announced in London, Eng., of Sir William H. Bailey, a prominent British engineer. Among his many accomplishments was the design and promotion of the Manchester Ship Canal.

The death occurred in Kingston last week of Mr. John Hazlett, well known in marine engineering, having been for years chief engineer of the Calvin and Hepburn Companies.

Mr. Oswald Gurney Carscallen, the Toronto representative of the Asphalt and Supply Company, Limited, died last Sunday at his home in Toronto after two months' illness. Mr. Carscallen was born in Hamilton and educated at the University School, Port Hope, and at Upper Canada College. Until three years ago he was vice-president and secretary-treasurer of the Gurney-Tilden Foundry Company at Hamilton. Mr. Carscallen had become very popular among the municipal and highway engineers and road contractors in Ontario during the three years that he was interested in paving work, and his death at the age of only forty-five years will be greatly regretted.

REVISION OF UNITED STATES ROAD LAWS.

A committee of the American Highway Association has been appointed to assist in the revision of the road laws of the various states in an endeavor to codify and simplify them and render them more uniform. The comprehensive plan which has been evolved will eventually result in a more uniform system of laws dealing with road matters. It is well recognized that most of the road legislation in various states is antiquated, and in many instances, obsolete. Many of the road laws are one hundred years old. There is little uniformity in the laws among the states. These facts appear as serious obstacles in the way of those who are seeking to give the entire country a network of improved highways.

It is probable that as a result of this movement the Governors of the various states will co-operate to urge upon the legislatures the appointment of commissioners, who will revise and simplify the laws.

THE FIFTH ANNUAL GOOD ROADS EXHIBITION.

The Public Roads and Highway Commission of Ontario will have an exhibit at the Good Roads Exhibition of the American Road Builders' Association, which is being held in Philadelphia, December 9th to 12th. In addition to some eighty-five commercial exhibits, which had been assigned before the end of November, and which figure will likely assume a materially larger dimension before opening day, there will also be extremely interesting and instructive exhibits from a large number of the state highway departments, leading cities, engineering schools and colleges. The United States Department of Agriculture will show the road models prepared by the Office of Public Roads.

The Ontario Highways Commissioners, Messrs. McGrath, McLean and Rankin, and Mr. Wagner, Secretary of the Commission, will be in attendance. Mr. A. T. Laing, Department of Highway Engineering, University of Toronto, and numerous road engineers throughout Ontario, Quebec as well as representatives from Western Provinces, have signified their intention of being present.

The officials in charge of the convention arrangements state that from present indications the forthcoming exhibition will be by all odds the largest and most complete that has ever been held. Every effort has been made, so far as possible, to include in this exhibition all the newest labor-saving machinery, methods and appliances, so that altogether, the exhibition will be an accurate and striking record of progress. Several important departures are promised by manufacturers in their respective lines, and the exhibition will afford those interested in the purchase and use of road machinery and materials an excellent opportunity for inspection and comparison.

A detailed programme of the technical features of the Convention appeared in *The Canadian Engineer* for November 20th.

COMING MEETINGS.

AMERICAN INSTITUTE OF ARCHITECTS.—Forty-seventh Annual Convention, to be held in New Orleans, La., December 2nd, 3rd and 4th. Secretary, Glenn Brown.

AMERICAN SOCIETY OF REFRIGERATING ENGINEERS.—Annual Meeting will be held in New York, December 2nd to 5th. Secretary, W. H. Reed, 154 Nassau Street, New York City.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—The Annual Meeting will be held in New York, December 2nd to 5th, 1913.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS.—Annual Meeting to be held in New York, December 10th to 13th. Secretary, C. D. Odsen, Polytechnic Institute, Brooklyn, N.Y.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS.—Seventh Annual Convention will be held at Great Northern Hotel, Chicago, December 29th to 31st. Secretary, I. W. Dickerson, Urbana, Ill.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

SHORT COURSE IN HIGHWAY ENGINEERING.

The last Illinois legislature passed a law regarding roads and bridges which introduced new principles and methods concerning the construction and maintenance of roads and bridges; and the law also created the offices of county superintendent of highways, and provides for the possible appointment of township or district superintendents of highways. In view of the new principles of administration introduced by this law, and also in consideration of the entirely new duties devolving upon the county and township superintendents of highways, and further, on account of the recent radical changes in the methods and materials of hard road construction, due to the increasing use of automobiles, the Civil Engineering Department of the University of Illinois will offer a course in highway engineering from January 19th to January 31st, 1914.

There will be no charges of any kind by the University; and the course will be open to anyone, without examination or other condition, who aspires to be appointed to the position of either county or township superintendent of highways, and to any others interested in the maintenance or construction of roads.

The lectures will cover the various phases of highway engineering; and will be given by members of the staff of the Civil Engineering Department of the University of Illinois, and by Mr. A. N. Johnson, State Highway Engineer, and members of the staff of the Illinois Highway Commission. The laboratory exercises are to show the methods of testing and using the materials employed in ordinary road construction, such as hydraulic cement, concrete, tar, asphalt, road oil, etc. It is expected to have several pieces of road machinery on exhibition with experts in charge to explain the manipulation and method of using each. In the evenings there are to be semi-popular lectures, which will be instructive to highway engineers and others interested in road improvement.

AMERICAN MANUFACTURE OF DIESEL ENGINES

Most of the important European manufacturers of large steam and gas engines are largely concentrating their energies on building Diesel engines, and have such a large number of orders that to make prompt deliveries is practically impossible. It has for some time been a subject of much comment in view of the highly successful business being done in the Diesel engines by many European concerns, that no attempt has been made to build in America a full line of Diesel engines of a design which has proved to be a commercial success in actual use.

It should be remembered that notwithstanding the increase in the price of fuel oil, the actual cost of fuel oil and its relative cost, as compared with coal, is generally much lower on this side the Atlantic than in Europe. Also, that oil suitable for Diesel engines is a by-product which will always be available in ample quantities as long as the present large consumption of gasolene and kerosene exists. Many large new oil fields are also being developed in this country, in the United States and in Mexico.

Not only are Diesel engines said to offer many advantages for central station units, factory and other isolated power plants, and railway service, but are particularly desirable for marine work, where weight and space saved is of prime importance. The Diesel oil engine eliminates the boilers, with their necessary handling of coal and ashes; also pumps, and many other accessories characteristic of steam equipment. The space so saved, and the coal-bunker space, can be used for cargo, and the liquid fuel, handled by pumps, and requiring less than one-third of the room required for coal, can be stored in the ship's double bottom. In view of these facts, there seems to be no reason why there should not be a broad field for this type of engine.

An announcement has just been made that a corporation has been formed with a New York State charter to engage in the manufacture on an extensive scale of a full line of Diesel engines, both stationary and marine, for the American countries. In addition to American interests, the company has behind it a number of Swedish capitalists, who now control the Swedish Diesel Motor Company (Aktiebolaget Diesels Motorer), which company started building these engines in 1898, and many of their designs of the most important features peculiar to this type of engine, such as fuel pump, atomizer, details of pistons, etc., have been adopted by other European builders.

The new corporation will take over the plant and organization of the McIntosh & Seymour Company, of Auburn, N.Y., builders of steam engines, and the construction of both types will proceed under the one organization, the name of which has been changed to McIntosh & Seymour Corporation. Mr. Edwin S. Church, formerly superintendent of the Akron plant, International Harvester Company, will be president; Mr. J. A. Seymour, formerly president of the McIntosh & Seymour Company, will be vice-president, with charge of engineering.

AGRICULTURAL ENGINEERS.

The American Society of Agricultural Engineers is holding its Seventh annual convention in Chicago. Dec. 29th to 31st, 1913. From a lengthy program we select the following items as of special interest to municipal officials, irrigation engineers and those more closely connected with rural development:—

(1) Farm Sanitation, with Special Reference to Water Supply and Sewage Disposal.—Paul Hansen, Engineer, Illinois State Water Survey.

(2) The Design of Permanent Farm Buildings.—E. S. Fowler, Universal Portland Cement Co.

(3) Standardization of Wagon Wheels and Tires.—E. Parsonage, John Deere Wagon Co.

(4) Concrete in Drainage and Irrigation.—C. W. Boynton, Universal Portland Cement Co.

(5) Small Motor Applications for Farm Work.—C. J. Rohrer, General Electric Co.

(6) The Five Winnipeg Motor Contests, and Lessons to be Drawn from Them.

(7) Address.—C. R. Richards, University of Illinois.

(8) Extension Work in Agricultural Engineering.—F. M. White, University of Wisconsin.

The secretary, Mr. I. W. Dickerson, Urbana, Ill., states that immediately after the close of the convention a brief summary of the papers and discussions will be prepared and will be sent to any one interested.

The Toronto branch of the Canadian H. W. Johns-Manville Company, Limited, announces its removal to 19 Front Street East. This new store and warehouse has a floor area of approximately 35,000 sq. ft., and is situated in the heart of the wholesale district. In their new quarters this firm will be able to carry a larger stock and have ample space for the display of their complete line of specialties.

The Pedlar People, Limited, of Oshawa, have moved their Toronto branch from Bay Street to a new building at the corner of College and Markham Streets, where they have a greater floor space, and will be able to carry a more complete stock of sheet metal work of all kinds, including culverts, flumes, drains, roofing, fire-doors, metal buildings, etc.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20875—November 21—Authorizing C.N.R. to construct across Winnipeg Electric St. Ry. Co., near Helen Street and near Pembina Street, Winnipeg, Man., subject to certain conditions.

20876—November 22—Rescinding Order No. 19310, dated May 16th, 1913.

20877—November 24—Authorizing C.P.R. to construct siding for Quaker Oats Co. in City of Peterboro, Ont., mileage 24.3.

20878—November 1—Directing C.N.R. to furninsh a daily passenger service west of Alsask, Sask., satisfactory to an Engineer of the Board; said service to be put into effect not later than Nov. 10th, 1913.

20879—November 24—Directing G.T. Ry. to construct spur from its railway on south side of Kaministiquia River to factory and plant of Mount McKay Pressed Brick Co. ot Fort William, Ont., adjacent thereto, crossing two city roads and tracks of St. Ry. Co. in said City of Fort William, subject to and upon certain conditions.

20880—November 24—Authorizing G.T.P. Ry., subject to inspection by Dept. Public Works of B.C., after crossing is constructed, to construct main line across Government Road in S.W. ¼ Sec. 11-11-5, Coast Dist. B.C., at mileage 400 Prince Rupert East.

20881—November 24—Authorizing G.T.P. Branch Lines Co. and C.P.R. to operate their trains over crossing, in East Half of Sec. 23-17-20, W. 2 M., Sask., without their first being brought to a stop.

20882—November 24—Authorizing G.T.P.Ry. to construct Lake Superior Branch, at mileage 17.9 across highway between Cons. 3 and 4, Tp. Oliver, Ont.

20883—November 24—Establishing collection and delivery limits of Express Companies in Town of Leamington, Ont.

20884—November 24—Extending, for a period of one month, from date of this order, time within which C.P.R. complete extension of siding for Quinlan & Robertson in Lot 10, Con. 8, Tp. Huntingdon, Co. Hastings, Ont.

20885—November 24—Authorizing G.T.R. to construct siding into the premises of Pollard Manufacturing Co., Limited, north of Buttery St., Niagara Falls, Ont., subject to terms of consent of said city and certain conditions.

20886—November 25—Extending, for a period of thirty days from date of this Order, time within which C.P.R. complete work of fencing portion of right-of-way from mileage 6.8 to 7.6, on east side of track, and repairing fences on west side of track, on Kingston and Pembroke Branch.

20887—November 21—Approving plan showing two new abutments for replacing piers at C.P.R. bridge, at mileage 35.4 on Chalk River Subdivision.

20888—November 21—Authorizing C.N.C.R. to construct bridge to carry its line over Indian River, Tp. Richards, Co. Renfrew, Ont., at mileage 107.85 from Ottawa.

20889—November 25—Authorizing C.N.R. to construct across public road between Secs. 14 and 15, Tp. 26, R. 26, W. 3 M., Sask., Alsask Southeasterly Line.

20890—November 25—Authorizing G.T.R. to construct siding, from siding serving Queenston Quarry Co., Limited, north of road allowance between Twps. Stamford and Niagara, Co. Lincoln, Ont., into premises of S. W. Marchment on Lot 48, Tp. Niagara (near St. Davids).

20891—November 20—Directing that within 30 days from date of this Order, C.N.R. submit for approval of Engineer of Board detail plans showing proposed half-interlocking plants to be installed, as required under Orders Nos. 5598, 6751 and 7291; work of installing said half-interlocking be completed within three months after approval of plans. 2. Cost of putting in diamonds at said crossings be borne and paid by City of Edmonton; and cost of providing, maintaining and operating half-interlockers be paid half by city and half divided equally between railway companies. 3. Leave reserved to G.T.P. Ry. to appeal to Supreme Court upon question whether in view of agreement between it and city, dated Sept. 29th, 1908, it is competent for Board to apportion cost of such protection as provided in paragraph 2 of Order 4. 4. Order No. 14994, dated Sept. 11th, 1911, is rescinded; recission to take effect upon installation and completion of interlocking plants herein required.

20892—November 25—Authorizing T.H. and B. Ry. to construct spur for the Egg-O Baking Powder Co., Limited, Hamilton, Ont.

20893—November 25—Directing that C.P.R. erect fences along portions of right-of-way near Savona, B.C., work to be completed within three months from date of this Order. And rescinding Order No. 17358, dated Aug. 27th, 1912, in so far as it relieves railway company from erecting fences along said portions of railway between Savona and Pennys.

20894—November 24—Authorizing Rural Municipality ot Hillsburgh, No. 289, Sask., at its own expense, to construct highway across C.N.R. at a point 250 feet west of west switch, D'Arcy, Sask.; railway company plank said crossing, and municipality do necessary grading.

20895—November 25—Approving location and detail plans of Windsor, Essex and Lake Shore Rapid Ry. Co station on the Talbot Road, Town of Maidstone, Tp. Sandwich South, Ontario.

20896—Authorizing C.P.R. to open for traffic that portion of double track from mileage 121 to Broadview, at mileage 131.4, Sask.

20897—November 25—Authorizing C.P.R. to construct, at grade, its Snowflake Westerly Branch across nine (9) highways, mlieage 0 to 9.10, Manitoba.

20898—November 25—Authorizing C.P.R. to construct, at grade, proposed switching lead on Eastern Division, Smith's Falls Sub. Div., at mileage 123.0 from Montreal, across public road between Cons. 3 and 4, Tp. Montague, Co. Lanark, Ont.

20899—November 27—Approving revised location C.N. Montreal Tunnel and Terminal Co., Limited's, tunnel line from St. Antoine St., to junction with its main line, at Montreal, Que.

20900—November 26—Approving C.N.R. plan of freight shed proposed to be erected at St. Albert, Alta., as required under Order No. 20765, dated Oct. 31st, 1913.

20901—November 25—Authorizing G.T.R. to construct siding into premises of Harris Abattoir Co., Limited, in Lot 10, Con. 1, Tp. Barton, now City of Hamilton, Ont.

20902—November 25—Directing that G.N.R. construct an open ditch of adequate width and depth, with bottom ot uniform grade, on north side of its railway, from point marked "A," being at Hjorth Road, to point marked "B," about 2,000 feet therefrom; at Tynehead Station, B.C.; drainage of land south of track to be looked after by Municipality in connection with its road construction.

20903—November 25—Authorizing C.P.R. to construct spur for William Rutherford, at Stephen, B.C.

20904—November 25—Authorizing C.P.R. to construct siding for National Builders' Supply and Enamel Concrete Brick Co., Limited, Montreal, Que., from a point on existing siding in Lot Cadastral No. 323, Range St. Pierre, delaCabane Ronde, Parish of St. Henry de Mascouche, Co. L'Assomption, Que., mileage 14.81 from St. Martin Jct.

20905—November 25—Authorizing Government of Sask., at its own expense to construct highway over G.T.P. Ry. near N.E. corner of Sec. 17-38-26, W. 2 M., Sask.

20906—November 27—Authorizing Dept. Public Works, B.C., to construct, at its own expense, an overhead highway crossing over G.T.P. Ry. at a point about 127 miles (G.T.P mileage) from Prince Rupert and near Fiddler Creek, B.C.

Tarvia

Preserves Roads
Prevents Dust~

Brant Road, Galt, Ont., Canada. Constructed with Tarvia Modern Pavement.

Of Interest To Taxpayers

A cloud of dust behind an automobile means that the road surface is being destroyed—blown away. It also means that the road is unfit for modern traffic—that it has been built in the old way intended for slow-moving, horse-drawn traffic.

The science of MacAdam has been re-written these last few years. A mineral binder is no longer enough to hold the stone together.

Something stronger is needed, and the use of Tarvia is the logical and necessary answer to a difficult problem.

In the tarviated road, there is a matrix of Tarvia around each stone, holding it firmly to its work and preventing it from shifting. There is no internal movement, and the attrition of traffic is reduced to a minimum.

If the road is built with Tarvia the extra cost of the treatment is more than made up in longer life and reduced maintenance costs.

Tarvia is made in three grades—"Tarvia X" is a dense, viscid coal tar product of great bonding power, suitable for building macadam roads; "Tarvia A" and "Tarvia B" are thinner grades suitable for roads already in use, to preserve them and make them dustless.

Booklets on request.

RAILWAYS—STEAM AND ELECTRIC.

Hamilton, Ont.—The city council has decided not to sign any agreement with Mr. Webb providing a new east end incline until he has given the council proof that the present incline is in working order. An interested citizen of Hamilton has stated his willingness to build inclines on Wentworth Street and Sherman Avenue, leaving no grade crossings, providing the city will grant the necessary approaches, lands, and rights.

Hespeler, Ont.—The Hespeler board of trade has passed unanimously a resolution asking the town council to carry a resolution similar to those passed by other municipalities interested in the proposed Hydro-Electric Railway scheme.

London, Ont.—The directors of the London and Lake Erie Radial Railway Company have been petitioned to construct an extension through Elgin from Union to Sparta, and further, if possible, to Port Bruce.

Montreal, Que.—The board of control has submitted the whole matter of the offers of the Montreal Tramways Company and the Canadian Autobus Company for a subway service to the city engineers for a report. The board will also write several cities in the United States for information bearing upon the proposition.

New Westminster, B.C.—At the joint conference of representatives from Burnaby, Westminster, and Coquitlam, with the B.C.E.R., it was made known during the discussion of the proposed bridge over the Brunette River, that the B.C.E.R. has in view a cut-off into Westminster on the Burnaby Lake line. With regard to the extension of the B.C.E.R. over the proposed Brunette River Bridge, Mr. F. L. McPherson, the Burnaby municipal engineer, submitted a profile requiring a high-level bridge over the river, and a small bridge over the proposed cut-off. The suggestion was made, and will be considered by the B.C.E.R., however, that the two new car line grades—the cut-off and the Columbia Street East extension to the North Road—should be made to intersect.

+—Ottawa, Ont.—A contract has been let by the Intercolonial Railway Company to the HALL SWITCH AND SIGNAL COMPANY for the installation of a telephone train-despatching line between Moncton and St. John, N.B.

Port Arthur, Ont.—The Port Arthur council has demanded that provision must be made to have the main line of the street railway from Current River to Hodder Avenue some time in the future if it became necessary.

St. Thomas, Ont.—The finances of the London and Lake Erie Railway and Transportation Company at present do not warrant a $17,000 expenditure as half the expense of the construction of a new double track on Talbot Street. The matter will be brought to the attention of the board of directors at its next meeting. The committee dealing with the question were approached also by officials of the M.C.R. for the purpose of getting consent to construct a switch from the street railway tracks to the M.C. yards. Consent for such a switch has been secured from the Dominion Railway Commission, and the L.E. Railway and Transportation Company committee finally decided to recommend that council consent to the company entering M.C. property from the tracks on Wellington Street the company to pay the cost of keeping the road in order, and to pay the city $1 for every car hauled over the line. In this way the First Avenue subway will be avoided.

Toronto, Ont.—The Railway Commission Board has ruled in connection with the application made by the Canadian Pacific Railway Company for approval of its plan for new steel trestle required for a double track at the Don viaduct in Toronto, is that the work is necessary and must be undertaken, but that a street opening must be provided, the extra cost of $3,000 to be paid by the city.

GARBAGE, SEWAGE AND WATER.

East Angus, Que.—A by-law to provide for the issuing of debentures to the amount of thirty thousand dollars at six per cent., to provide for the completion of the water and sewer system, was brought before a public meeting of the ratepayers and approved.

Hamilton, Ont.—After the presentation of a financial statement to the city council by Mayor Allan, that body decided on a majority vote not to submit the sewer bylaw to the ratepayers. Two weeks ago, the council decided unanimously in favor of submitting this by-law asking for $650,000 for a storm overflow sewer.

Hull, Que.—A delegation representing the city of Hull has visited Quebec to interview the Premier and the private bills committee concerning the Ottawa bill now before the Legislature with regard to the Gatineau Lakes water scheme. They asked that certain amendments be embodied in the measure before the bill will be allowed to pass. One amendment confines Ottawa to certain townships and objects to the granting of exclusive rights to all the lakes in the Gatineau district as asked by Ottawa. Another will make it compulsory for Ottawa to supply Hull with water, if desired, and not optional as in the original clause of the bill. Also the bill has been amended so as to exempt Hull from inclusion in the clause regarding Ottawa's powers of expropriation of lands, etc. And finally another clause has been added to the bill whereby the powers and rights of the act shall not have priority over any powers and rights given Hull by its charters and amendments.

Ingersoll, Ont.—The report of Consulting Engineer Weston of Boston, who was engaged in connection with the proposed sewerage system for Ingersoll, has been prepared and received by the Sewerage Committee. After receiving consideration from this body, it will be forwarded to the town council.

London, Ont.—Engineer E. S. Smyth of Winnipeg, one of the western engineers of the Chipman firm, is at present in London assisting on the plan work for the new storm sewerage system. Mr. W. A. MacGregor, also an expert of the Chipman firm, will be transferred to this work on January 1st, and construction on three sections is to be commenced simultaneously in the spring—Carling's Creek, Egerton and South London.

Medicine Hat, Alta.—By-laws have been passed at Medicine Hat, which total an expenditure of $500,000 for next year's work. Two of these by-laws provide for extensions to the city's water and sewer systems.

Ottawa, Ont.—It has been announced at Ottawa that a special meeting of the International Waterways Commission, to be held at Washington in January, will deal with the application of Winnipeg to convey water from Shoal Lake to the city, and also with the joint application of the Michigan Power Company and the Lake Superior Corporation for power to dam the St. Mary River at the Soo and develop the power for distribution.

▲—**Toronto, Ont.**—Tenders will be received up till December 16th for one overhead hand-operated crane, having a working load of 40,000 pounds, for the main pumping station. Plans and specifications may be obtained from the Purchasing and Accounting Dept., City Hall, Toronto. Signed, H. C. Hocken (Mayor), Chairman Board of Control.

▲—**Toronto, Ont.**—Tenders will be received up till December 16th, 1913, for the laying and jointing of a 36-inch water main from the high level pumping station to West Toronto. Plans and specifications may be obtained from the Waterworks Section, Department of Works, City Hall, Toronto. Signed, H. C. Hocken (Mayor), Chairman, Board of Control.

+—**Toronto, Ont.**—The city council has awarded contracts for sewers to J. F. CONNOLLY on Benlamond Avenue at $1,942; to J. H. McKNIGHT CONSTRUCTION COMPANY on Dufferin Street at $14,445, and on the Midway Drainage system at $4,445.

Vancouver, B.C.—Alderman Black, chairman of the water committee, has been informed by Mr. H. H. Stevens that the public works department at Ottawa will not sanction any scheme for the laying of Point Grey partnership main across False Creek at Granville bridge, that does not specify that the pipe shall be 40 feet below tide. Since it will doubtless take years before the Dominion Government carry out their extensive plans, the committee favor the laying of the pipe at any reasonable depth, so long as it would not in the meantime interfere with any work that might be undertaken by the Government, and also, so that it could be removed when the occasion required.

+—**Victoria, B.C.**—The contract for the construction of the reinforced concrete flow line for the Sooke Lake waterworks system has been awarded to the PACIFIC LOCK JOINT PIPE COMPANY. The company's bid was for $329,760 for a 40-inch pipe line; but the size of the pipe has since been increased to 42 inches. The question of the manner in which the pipe, when fabricated, will be distributed and laid along the pipe line grade, whether by the contractors or by the city, will be decided when the contract is before the Council for signature.

Victoria, B.C.—Alderman McNeil has given notice of a motion to request the finance committee of the city council to make the necessary arrangements with the Pacific Lock Joint Company in order that the work on the concrete flow line pipe may be begun immediately, instead of waiting till a further sale of waterworks debentures has been made.

Victoria, B.C.—Two tenders for the riveted steel pipe have been received, one from the Macdonald Godson Company of Vancouver, at $485,203, which is over $40,000 in advance of the July tender, and the other from David A. Chesney of Craigdarroch Castle, at $426,080. They have been referred to the water commissioner and consulting engineer for a report.

LIGHT, HEAT AND POWER.

Medicine Hat, Alta.—Two of the by-laws passed by the Medicine Hat burgesses recently provide for the necessary expenditure to make installations and extensions to the city's gas and electric light systems.

Niagara Falls, Ont.—At the last meeting of the Niagara township council, a motion was carried to request the clerk to notify all parties holding Hydro-electric petitions to return the same to the council at once, in order that they may be forwarded to the Hydro-Electric Commission without delay.

+—**Peterborough, Ont.**—A large contract has been received by the WILLIAM HAMILTON COMPANY from the Charlton-Englehart Power Company, of Ontario, for the water-wheels and other machinery required for a generating station to supply power to the towns of Charlton and Englehart.

St. Thomas, Ont.—Mr. J. T. Lynn of Detroit, natural gas expert, whose advice the city engaged, has reported to the city council, strongly recommending the city to contract for a supply of natural gas, if an agreement can be made whereby the supplying company will be paid on a percentage basis at a rate permitting the city to sell to consumers at 45 cents net in summer and 30 cents net in winter. Mr. Lynn points out that whether the city retains an artificial plant or takes natural gas, $20,000 must be spent on new mains. If the artificial plant is continued, over $60,000 additional will be needed to put it in condition to handle existing business in a proper manner. The city expects to conclude negotiations with the Southern Ontario Gas Company for a supply from Tilbury field next week.

BRIDGES, ROADS AND PAVEMENTS.

Fredericton, N.B.—Mr. P. M. Monserrat of Montreal, one of the designing engineers for the Quebec bridge, has had a conference with Premier Flemming, and it is understood will make an independent report to the Provincial Government on the question of the construction of the proposed bridges across the St. John and Kennebeccasis River for the St. John Valley Railway.

Montreal, Que.—The City Council has adopted the following motion, which will be presented at Quebec as a proposed charter amendment: "that the City Attorney be requested to insert in the city's bill now before the Provincial Legislature a clause compelling the city to set aside each year for the laying of permanent pavings a sum of not less than $1,500,000, to be taken out of the funds raised in virtue of Article 343 of the charter."

Ottawa, Ont.—The Government has approved of the subsidy contract for the Second Narrows bridge at Vancouver, amounting to three hundred and fifty thousand dollars. The money now being available, the work can proceed forthwith.

Ottawa, Ont.—Representative citizens, who have appeared before the Board of Control in connection with a temporary structure at the Billing's bridge site, have been assured that the board will seriously take into consideration the suggestion to build a pontoon bridge to keep open communication. The city engineer will report on it and the

county will again be approached in the matter. The estimated cost of the pontoon bridge is $3,500.

Perth, Ont.—The county of Lanark recently sold $40,000 good roads debentures to a Toronto house at 97.

Peterborough, Ont.—The city of Peterborough has accepted, with the approval of the Government, the offer of the C.P.R. to place a swing bridge with a 37-foot opening on each side of a pivot pier in the new bridge being erected by the railway company over the Otonabee River on the line of the Trent Canal at Peterborough.

+—South Vancouver, B.C.—The municipal council has awarded a contract totalling $438,494.93 for the paving of Main Street from Sixteenth Avenue to River Road. The firm to secure the contract is the DOMINION CREOSOTING COMPANY, and the material stipulated is creosoted wood blocks.

▲—Toronto, Ont.—Tenders will be received up till December 16th, 1913, for asphalt, paving block, granite or stone setts, etc. Plans and specifications may be obtained from the Accounting and Purchasing section of the Department of public works, City Hall, Toronto. Signed, H. C. Hocken (Mayor), Chairman of the Board of Control.

+—Toronto, Ont.—The city council has awarded the contract for asphalt pavement on Grange Avenue to the CONSTRUCTING AND PAVING COMPANY, price $6,210; for asphalt concrete pavement on two sections of Givens Street to the CONSTRUCTING AND PAVING COMPANY for $3,980 and $3,023, respectively; for concrete pavement on Danvers Avenue to the RIVERDALE CONCRETE PAVING COMPANY, price $241; for brick block pavement on Derby Lane to the GRANT CONTRACTING COMPANY at $2,595; for asphalt pavements on Alma Avenue to the COMMISSIONERS OF WORKS; on Arlington Avenue to the GODSON CONTRACTING COMPANY, at $8,400; on Carus Avenue, to the CONSTRUCTING AND PAVING COMPANY, at $1,822; on Johnson's Lane, Rushton Road, and Wells Hill Avenue, to the COMMISSIONER OF WORKS; for bitulithic pavement on Bain Avenue, to FRED. REID, at $1,275; on Springmount Avenue, to the BRITNELL CONTRACTING COMPANY, at $10,350; on Spears Avenue, to the RAMSAY CONTRACTING COMPANY, at $1,000.

Toronto, Ont.—Mr. Frank Barber, York township engineer, has submitted his report to the township council regarding the proposed high level bridge across the West Don on Eglinton Avenue. He claims that the bridge at this location is not only necessary to traffic, but could be available also for radial lines, such as the Toronto Eastern and the Hydro Radial from Port Perry, should the commission select the north-east route. The bridge would be 1,000 feet long, 100 feet high and would cost $150,000 to $200,000. The council passed a resolution requesting the commission to select the northerly route and bring the radial into the city via Eglinton Avenue.

Vancouver, B.C.—The civic board of works has recommended that tenders for $325,000 worth of new pavements be called for at once; and it is expected that these will be advertised before the end of the month.

Winnipeg, Man.—Salter Street subway supporters are holding meetings for the purpose of taking action to have the city council build the proposed subway.

Winnipeg, Man.—The board of control has practically decided to employ an expert on subway planning and construction to advise on the plans and specifications for subways at Salter Street and Talbot Avenue, Elmwood. It is not at all likely that work will be begun on these until the end of next year.

INDUSTRIAL WORKS.

Coderich, Ont.—In connection with the wreck enquiry, important improvements needed for the proper equipment of Goderich harbor were emphasized, e.g., a modern foghorn suitably placed, a well-manned lifeboat station and adequate lights, and the dredging of the harbor basin to a greater area.

+—Ottawa, Ont.—The contract has been awarded by the Cabinet Council for the ocean section of the Halifax terminal scheme. The successful tenderers are FOLEY BROS., WELCH, STEWART, AND FAUQUIER; and the contract price is $5,208,743. The works involved are docks, wharves, and subsidiary equipment; and operations are to be rushed. Two sections of the water front improvement scheme remain to be put under contract.

+—Ottawa, Ont.—The contract has been awarded by the Dominion Cabinet Council to ANDREW McCONNELL for the construction of a wharf at Summerland, B.C., costing $12,365.

+—Ottawa, Ont.—The Dominion Government has awarded to the COASTAL DREDGING AND CONSTRUCTION COMPANY the contract for dredging to the extent of $5,945 at Glace Bay, N.S.

+—Ottawa, Ont.—The Cabinet Council has awarded to ELZEAR CARON the contract for the construction of a wharf at St. Jean Port Joli, Quebec, at a cost of $7,855.

+—Ottawa, Ont.—The Dominion Legislature has awarded the contract for dredging at Oak Point, N.B., to the MARITIME DREDGING AND CONSTRUCTION COMPANY at 19 cents per cubic yard, or a total of $6,337.

+—Ottawa, Ont.—The contract for dredging 300,000 cubic yards of sand at Sand Hearts, at the mouth of the Fraser River, B.C., has been awarded by the government to the NAVIGATION DREDGING COMPANY, the contract price being $70,500.

Ottawa, Ont.—Tenders will be received up till December 22nd for the construction of an extension to the wharf at Grands Mechins, County of Rimouski, Que. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

Ottawa, Ont.—Tenders will be received up till December 22nd for the construction of a line of wharves and dredging Tidal Basin at Rimouski, County of Rimouski, Que. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

Ottawa, Ont.—Tenders will be received up till December 10th for the construction of a breakwater at Blandford, Lunenburg Co., N.S. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

Ottawa, Ont.—Ulric Valequette, supervising engineer of the Public Works Department, has left for Esquimalt, B.C., to choose a location for the new dry dock in that city. It will be an almost complete duplicate of the dock now being constructed at Quebec.

Port Moody, B.C.—A committee has been appointed by the local Conservative Association to draw up a memorial to Colonel J. D. Taylor, M.P., asking the Government to extend the Port Moody wharf fifty feet further into the Inlet or to dredge the channel off the wharf to permit large vessels to come alongside.

St. John, N.B.—Following the promise of the Hon. Robert Rogers to have an expert look over the St. John harbor situation, Mr. A. D. Swan of Montreal, is in St. John going over the ground already developed, inspecting the facilities now in course of construction, and ascertaining as far as possible in what direction and upon what lines future harbor development must be laid out. Mr. Swan may also report upon the new eastern harbor at Courtnay Bay, and also upon the suggested extension of the new west side wharves to the length of 1,000 feet.

+—Toronto, Ont.—The city council awarded a contract for stop valves to DRUMMOND, McCALL & COMPANY in connection with the tender called for brass and bronze castings, cast-iron pipes, hydrants, etc.

Vancouver, B.C.—Colonel Sam Hughes, of the Ottawa Government, has approved of the ground plan for the improvement by the park board of Vancouver of the property at the head of Coal Harbor, Vancouver.

MISCELLANEOUS.

Brandon, Man.—Dr. Pickard, who is engaged upon the matter of securing for Brandon an incinerator, is waiting for a definite price from the Decarrie Company, of Minneapolis

for a destructor suitable for the growing needs of the city before placing the whole matter before the city council for its consideration.

Calgary, Alta.—The Lake of the Woods Milling Company intend to build an elevator, mills and a warehouse in Calgary, and at the present time the company is taking the matter up with the Government.

Fort William, Ont.—Construction work on the Stanley Avenue sewer, which has been retarded owing to a controversy between the city and contractors and the Canadian Car and Foundry Company, will probably be resumed within a few days. The sewer has been completed on both sides of the plant, and it is thought that it will be run under the huge plant of the car company within a month's time.

London, Eng.—Sir Percy Girouard has refuted the notice that the new Canadian company of Armstrong and Whitworth will concern itself with armaments or shipbuilding. The company intends to manufacture high-grade steel for commercial purposes.

+—Ottawa, Ont.—The contract has been awarded by the Ottawa Cabinet to the WALLACE SHIPYARDS, LIMITED, North Vancouver, B.C., for the installation of oil-burning apparatus and construction of oil-tight flat in the tug "Point Ellice," at a cost of $4,386.

+—Ottawa, Ont.—A contract for the construction of a dump scow with a capacity of 260 cubic yards, was awarded by the Dominion Government to the WALLACE SHIPYARDS, LIMITED, at $8,475. The big scow is for use in connection with the extensive harbor improvements at Victoria, B.C.

Port Arthur, Ont.—Two steamers are to be put in drydock at Port Arthur this winter to undergo extensive repairs—the Athabasca of the C.P.R. upper lake passenger service, and the Alberta. The estimated cost of improvements to the two steamers is about $70,000. No confirmation of the report made some time ago that the Keewatin and Assiniboia would undergo repairs also in the Port Arthur dock has been given, though they will be overhauled either here or at the Collingwood plant.

St. Catharines, Ont.—The citizens of St. Catharines will vote upon the incorporation of a branch of the firm, Lord and Burnham, recommended as one of the best industrial concerns in the United States.

+—Toronto, Ont.—The city council awarded a contract to MR. R. D. WOOD for special castings in connection with the tender called for sundry orders of castings, valves, pipes, etc.

Vancouver, B.C.—Mr. Yarrow, shipbuilder, of Glasgow, Scotland, is examining possible building sites, charges for wharfage and harbor depths, etc., in connection with the possible construction of a shipbuilding plant at Vancouver.

+—Victoria, B.C.—The city council has awarded the contract for telephone wire to the lowest bidder, THOMAS WATSON, ESQ., at $426 a mile, or $10,650.

CURRENT NEWS.

Brandon, Man.—According to the report presented by Superintendent Antonisen to the city council committees on Friday, November 28th, the street railway receipts for November are in excess of those for the previous month to the extent of nearly $5 per day.

Brantford, Ont.—In connection with the construction of Lorne Bridge, the main retaining wall is completed; and Mr. Wright of the contracting firm, Wright, Hazzard and Cohen, states that, as he understands the situation concerning the second retaining wall, the railway has not submitted plans to City Engineer Jones for his approval, and instructions have not been given his firm to proceed with the work. Men are being laid off work, awaiting further developments.

Galt, Ont.—Difficulty of a financial nature, according to Mr. John Muir, president of the L.E. and N. Railway, has caused a temporary lay-off in the construction work on that railway. Much work must still be done between Brantford and Galt, before the line is completed, but it is expected that construction will commence again within a short time.

Lindsay, Ont.—The special Mud Lake Narrows bridge committee of the county council has met and discussed the bridge recently completed. Tenders were received for the bridge ranging from $1,786 to $6,467, while the final cost of the structure was $6,481.63.

Montreal, Que.—The council of the Montreal Board of Trade has passed a resolution earnestly protesting against any amendment to the city charter whereby the cost of paving the streets shall be made a charge upon the civic revenue. Copies of the resolution are being sent to Sir Lomer Gouin, the Montreal member of the Legislature, and Mayor Lavallee.

Moose Jaw, Sask.—Another street car service was opened recently at Moose Jaw, when Mrs. J. Darley Colley, in the presence of the Mayor and influential citizens formally opened the car line built to Boulevard Heights, about two miles from the centre of the city.

Ottawa, Ont.—The Dominion Dredging plant has had brought to Port Weller new dump cars of 1913 patent. They have the latest improvements in air brake and all dumping attachments. In addition there are expected at the plant this week three new 50-ton locomotives, a new drag line and a new steam shovel. The shovel is one of the largest made and has a bucket with a four-yard capacity. The Dominion Dredging Company has not made much progress as yet, but they expect soon to be ready for rapid operations with modern machinery.

Ottawa, Ont.—The Hydro-Electric and Ottawa Power commissions have completed a new contract between the city and Provincial Commission which will receive further consideration at Ottawa. It has been provided for a larger consumption of power upon a sliding scale giving much better terms to the city.

Ottawa, Ont.—When in the capital recently, Sir Donald Mann, vice-president of the C.N.R., said that the Canadian Northern would be "letting the daylight through Mount Royal" about December 10; and that already a mile of the tunnel had been widened to the regular size for the double track.

Redcliff, Alta.—The International Supply Company, will have in operation within the next month a drill on its oil leases northwest of Redcliff. The Medicine Hat firm will also set in operation here well drilling apparatus, and will use a double casing to bore through the gas down to oil.

St. Catharines, Ont.—The new extension of the Niagara, St. Catharines and Toronto Railway, between St. Catharines and Niagara-on-the-Lake, has been completed within a few miles of Niagara, and a regular passenger service has been commenced.

St. John, N.B.—Surveys have been completed for the western extension of the Aroostook Valley Railroad, which has been incorporated under the name of the St. John and Quebec Railroad, and work of construction will be commenced early in the spring. The rails will connect with the St. John Valley and other Canadian roads, forming a link in a transcontinental route.

Sydney, N.S.—According to the report furnished by President Gillies to the Board of Trade concerning the services of an ice-breaker for Sydney Harbor, the Government has provided for the services of an ice-breaker on the south coast of Nova Scotia. Sydney Harbor will in all likelihood receive the attention the Board of Trade has been endeavoring to obtain

Sydney, N.B.—Work on the extension of Sydney's "White Way" is progressing favorably, and there is a probability that a further extension may be requested.

Vancouver, B.C.—Agreements between the city, Esquimalt and Saanich in connection with the construction cost of the proposed north-west sewer system, have been presented to the city council. In view of the fact that Saanich may not be in a position to sign should the by-law to be submitted be defeated, Alderman Cuthbert urged separate agreements between all parties, instead of one including all.

Vancouver, B.C.—Work has been started on the new Provincial Government bridge over the Kootenay River near Nelson, known as the Taghun Bridge. The contract for this structure was recently awarded by the Provincial Government Public Works Department to Hodgson, King and McPhalen of Vancouver. The contractors now have materials on hand for

Why Lose Time "Shopping"

When You Can Buy Anything You Want

"Under One Roof"?

It is just as great a convenience to engineers, contractors and builders to be able to get their supplies from one house as it is to the general public to shop in a large modern department store. The rise of the department store has been the result of economic conditions.

Likewise our business has evolved into a departmental house in the mechanical world in obedience to the same economic law.

This bringing together of a vast number of lines and classifying them according to departments is the kind of combination in industry that makes for efficiency, economy and better service.

Canada's Departmental House for Mechanical Goods

Can supply you with material all the way from nuts to machine tools and oil engines

Our business is divided into about a dozen different departments, as follows:—Scale Department, Engine Department, Valve and Steam Goods Department, Pump Department, Electrical Department, Transmission Department, Railway and Contractors' Supply Department, Small Tool and Supply Department, Safe and Typewriter Department, and Motor Truck Department.

From time to time we advertise products from the different departments that we think readers of *The Canadian Engineer* are interested in, but you should not by any means infer that those are the only goods we handle.

In this new series of advertisements we wish to drive home the fact that we are literally a "Departmental House for Mechanical Goods."

All you need to do is to make known to us your requirements. Write, telephone, or call.

The Canadian Fairbanks-Morse Co.

LIMITED

"The Departmental House for Mechanical Goods"

2

the work, and Engineer Clyde Campbell of the Public Works Department is on hand to superintend the construction for the Government.

Vancouver, B.C.—Construction work on the drill scow to be used by Messrs. Henry, McFee and Macdonald, the contractors for the submarine work in connection with the new Dominion Government dock to be built on Burrard Inlet, has nearly been completed, and the boat is expected to be ready for launching next week. Dredging of the surface material that covers the rock bed of the dock site has been proceeding since October 17, and several thousand yards of dirt have been already taken out.

Vancouver, B.C.—The city engineer has announced that out of the $150,000 set aside some time ago by the board of sewers, about $100,000 has been spent, and the balance will be expended before the end of the year on the work in hand.

TRADE ENQUIRIES.

The following inquiries relating to Canadian trade have been received:—1886.—A South African importer asks to be put in touch with Canadian exporters of calcium carbide. 1900.—Samples and prices are asked by a South African importer. 1913.—A South African importer asks for catalogues and prices on Canadian-made agricultural machinery. 1915.—Samples and prices are asked for by a Port Elizabeth firm on Canadian wire. 1960.—A South African importer asks to be put in touch with Canadian exporters of shovels. 1961.—A South African importer asks to be placed in communication with Canadian exporters of axes. 2064.—A Durban firm of machinery importers asks to be placed in touch with Canadian exporters of calcium carbide. 2077.—A long-established British firm at Bordeaux, France, desires to correspond with Canadian exporters of rare minerals, especially wolfram, molybdenite, etc. 2081.—A Glasgow firm would like to hear from manufacturers of mica.

The names of the firms making these inquiries, with their addresses, can be obtained upon application to:—"The Inquiries Branch, the Department of Trade and Commerce, Ottawa," or the Secretary of the Canadian Manufacturers' Association, Toronto, or the Secretary of the Board of Trade at London, Toronto, Brandon, Halifax, Montreal, St. John, Sherbrooke, Vancouver, Victoria, Winnipeg, Calgary and Chambre de Commerce du District du Montreal.

MONTREAL MARKET LETTER

It would seem that there are now only three merchant furnaces operating in Canada, these being at Hamilton, Deseronto and Port Colborne. There were formerly two others, being located at Midland, but they are now the property of the Canada Iron Corporation. The Port Colborne furnace is a new one, and is being operated by the Canadian branch of an American company. It is stated in Montreal that this furnace, as well as the furnaces at Deseronto and Hamilton, are all keeping busy, and that at Port Colborne has orders on hand for months ahead. It is also understood that the Dominion Iron and Steel Company has been selling some of its output to foundries and other users. At the same time, the great bulk of its output is used right in its own works, and thus contributes to the industrial activity of the corporation.

It is stated here that Canadian foundries have plenty of work on hand at the moment. Unfortunately, future activity is very doubtful, few large contracts for delivery during the coming winter being reported. It is felt, however, that there is no use borrowing trouble, inasmuch as when the time comes matters will probably straighten themselves out again. It is encouraging to hear that stocks of consumers are low; since this will probably mean that before long they will have to be replenished. It is generally felt that buyers are holding off in the hope of getting lower prices, and it must be admitted that up to the present the situation seems to be mostly in their favor.

The pig iron situation is figured out something as follows: The competition is mostly from Buffalo iron, which, at a cost of $13.75 in Buffalo, $2.80 duty, and the same freight, would make $19.35 Montreal. Iron in Montreal is now quoted in store instead of on dock, the season of navigation being over. Altogether, prices show little change.

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.05 per 100 lbs.; best refined horseshoe, $2.30; forged iron, $2.20; mild steel, $2.05; sleigh shoe steel, $2.05 for 1 x ⅜ base; tire steel, $2.15 for 1 x ¾ base; toe caulk steel, $2.95; machine steel, iron finish, $2.10.

Pig Iron.—Canadian iron is quoted at $17 to $17.50 at the furnace, equal to about $19 to $19.50 Montreal. Summerlee, No. 1, ex-store, $22.50; No. 2 selected Summerlee, $22; and No. 3 soft, $21.50; while No. 3 Clarence is $20.50, all ex-store.

NEW INCORPORATIONS.

Georgetown, Ont.—The Century Pressed Brick and Tile Company, Limited, $250,000. J. W. Ramshaw, J. R. Peacock, D. Menzies.

Kelowna, B.C.—Kelowna Implement Company, Limited, $25,000.

Levis, Que.—The National Drop Forge Company, Limited, $49,000. J. B. Doris, E. Belleau, N. Belleau.

Montreal, Que.—Economical Gas, Light and Power Company, $1,000,000. A. Carrillo, L. Hoz, B. Bassi. Lachine Rapids Power Company, Limited, $500,000. W. K. McKeown, L. Choquette, J. R. Law.

Ottawa, Ont.—Canadian Contracting Company, Limited, $1,000,000. E. Belleau, N. Belleau, J. E. Labadie.

Thorold, Ont.—Inland Pulp and Paper Company, Limited, $200,000. G. H. Levy, A. H. Gibson, S. W. C. Scott.

Vancouver, B.C.—The Canadian Steel Studding and Manufacturing Company, Limited, $30,000.

Winnipeg, Man.—Linton-Hay-Lush Electric Company, Limited, $20,000. E. N. Linton, J. R. C. Hay, H. S. Lush, J. H. Brooke. The Rice Lake Gold Mines, Limited, $2,000,000. F. E. Evans, A. L. Anderson, C. Andrews.

It is understood that the report of the government cruisers, who recently completed cruising the timber on the limits in the Seymour Creek watershed offered to Vancouver by Mr. D. A. Robinson as a site for the proposed Seymour Creek reservoir, will state that the estimated value of the marketable timber thereon is $56,916.55. They estimate the amount of timber of all kinds at 124,000,000 feet, of this amount but 98,340,000 feet being accessible, and assume that the timber would be removed in five years, the cost per thousand feet being based on the estimate of accessible timber on the area in question, namely, 98,340,000 feet board measure. As the timber could not be taken out in a satisfactory manner by driving Seymour Creek or by a flume, it would be necessary to construct a railway from salt water, fourteen miles in length, and the cost of this, including right-of-way and terminal facilities, is placed at $125,000. It is also estimated that $90,000 would be necessary for equipment.

There are at present twelve sea-going vessels classed with Lloyd's which are propelled by Diesel engines and 25 others are being built. There has been a remarkable increase in the amount of tonnage classed in respect of vessels intended for carrying oil in bulk. Forty-five of these vessels of 202,005 tons were classed during the year, and there are at the present time 83 of 381,410 tons preparing and in course of construction under the supervision of Lloyd's surveyors. The use of wireless telegraphy and submarine signalling increases year by year. There are now recorded 1,932 vessels fitted with wireless installations, as compared with 1,392 at a corresponding date last year, and 806 fitted with submarine signalling apparatus, as compared with 630 last year. The return for the quarter ended September 30 shows that, excluding warships, there are 508 vessels of 1,987,254 tons gross under construction in the United Kingdom, as compared with 505 vessels of 1,846,829 gross tonnage in the corresponding quarter of last year.

Ground Water

must be kept out of the sewer. Less money will have to be spent on disposal plant if the amount of sewage to be treated is smaller. Every gallon of ground water that leaks into the sewer adds to the expense and seriousness of the sewage disposal problem.

"Compares Favorably with Hütte."

From an Engineer in California:

"I was favorably impressed by the list of associate editors, by the table of contents, and by the remarkably successful typography especially of the mathematical tables. It seems to me that you have gotten out a book of which Americans may well be proud, one which will compare favorably with Hütte, and which will reflect credit upon the profession in this country."

LIST OF SECTIONS

1. Mathematical Tables (40 pages)
2. Surveying, Geodesy, Railroad Location (112 pages)
3. Steam and Electric Railroads (120 pages)
4. Materials of Construction (134 pages)
5. Plain and Reinforced Concrete (90 pages)
6. Masonry, Foundations, Earthwork (80 pages)
7. Masonry and Timber Structures (128 pages)
8. Steel Structures (126 pages)
9. Hydraulics, Pumping, Water Power (84 pages)
10. Water Supply, Sewerage, Irrigation (110 pages)
11. Dams, Aqueducts, Canals, Shafts, Tunnels (104 pages)

COAST TO COAST.

Guelph, Ont.—Guelph comes third on the list of municipalities contributing to Hydro-Electric profits. It returns a surplus of 35 per cent. above the total operations, and is the equal of Berlin in this respect.

Hamilton, Ont.—Hamilton is expecting very favorable consideration from the Hydro-Electric Commission, when it announces next reductions in the cost of power purchased by municipalities.

Calgary, Alta.—In public utilities construction work, Calgary has expended almost seven million dollars, according to the statistics furnished in the report of the city controller. The sum of $2,921,160.05 has been laid out on city's water system, $1,915.078.96 on the street railway, and $1,781,136.68 on electric light.

Vancouver, B.C.—Double tracking of sections of the line west of Kamloops and east and west of Revelstoke will be completed early next spring, according to the statement of vice-president Bury of the Canadian Pacific Railway, when in Vancouver after conducting inspection on his way through from Winnipeg.

Vancouver, B.C.—Preparatory work is being carried on in Vancouver for the laying of pavement next year, to commence as early in the spring as possible. The city will lay between 4 and 5 miles of pavement next season, which has had to stand over owing to the prevalent financial stringency, and also other work that may be decided upon as urgent.

Montreal, Que.—In the month of April, work was started on the new buildings connected with the Angus shops operated by the C.P.R. at Montreal; and in five months all was completed, and the first steel freight car had been built. The addition to the shops has a capacity for manufacturing 10 steel freight cars a day, and from 8 to 10 steel passenger cars per month.

Winnipeg, Man.—A comparison between the collections and earnings of the civic light and power plant for October, 1912, and October, 1913, shows an appreciable growth in that department's business. For the former month, the collections were $25,552.57, and the apparent earnings $41,189.56; for the latter, the net collections $61,389.78 and the earnings $72,032.06. The amount of cash collections for 1913 is not complete, all the bills not yet having been paid.

Ottawa, Ont.—It has been announced that up to date a total expenditure of $4,372,000 has been made on the Hudson Bay Railway, of which almost one million has been used on the harbor at Port Nelson. This harbor construction has proven very difficult, owing to the tides and tremendous current. On the railway, 75 miles of steel have been laid, and another 135 miles have been graded for steel. Some 30 miles are in a stage close to completion; but construction has not yet been begun on 178 miles of the road. So far, work has proceeded from Le Pas toward Hudson Bay, but next year construction will be commenced from Port Nelson. The railway was to have been ready for operation by December 1st, 1914; but, owing to the scarcity of ties, it is now expected that completion will not be attained before December 1st, 1915—two years hence. At that date, upwards of $12,000,000 will have been spent, the harbor and terminal expenditure aggregating some millions of this.

Montreal, Que.—The C.P.R. has its programme all ready for next year. This includes the continuation of the programme for this year carried forward into the new year—the double tracking between Sudbury and Port Arthur; between Port Arthur and Calgary, which calls for 1,095 miles of trackage; between Calgary and Vancouver; between Brandon and Calgary; the double-track tunnel through the Selkirks; the double-tracking between Revelstoke and Vancouver; a line between Sedgewick and Edmonton—290 miles; two new lines from Bassano to a connection with Swift Current. Then there is the Weyburn branch, running south of and parallel to the main line in Saskatchewan and Alberta to a connection with the Alberta railway south of Lethbridge—a distance of 436 miles. There are several other smaller lines, ranging from 20 to 100 miles in trackage, which are included in the programme, which is to be steadily pursued next year as part of the policy undertaken two years ago, and which, when all is complete, will more than absorb the $100,000,000 which Sir Thomas Shaughnessy announced the company intended to spend on betterments and extensions.

Ottawa, Ont.—Optimistic reports on the present year of railway construction up to the present are being circulated from Ottawa. During the twelve months ending June 30th, 1912, the addition to operating railway mileage was 1,330 miles, which was a record; and it is understood that the year ending June 30th, 1913, will show an addition exceeding that of 1911-12 by some 500 or 600 miles. That is to say, from June 30th, 1912, to June 30th, 1913, some 1,900 miles were added to the operating mileage of the railways of Canada. Since June 30th last there has been intense activity in construction. During the year the Canadian Pacific has added several hundred miles to its lines, some of it being double-trackage in the West, but the greater part of it consisting of branches perfecting the service in the West. The work done by the other systems is largely of a nature which when completed will open up large areas to development, such as Northern British Columbia and Northern Ontario and Quebec. The coming session of the House will provide the means for pushing forward the gigantic task of laying down for Canada a national equipment, or development plant, in railways, canals and terminal ports adequate to the enormous growth which is to be expected in the course of the next few years. The year 1914 will be a period of great activity in public works and railway construction.

PATENTS.

Below will be found an up-to-date list of Canadian patents recently granted. It is furnished by Messrs. Fetherstonhaugh & Co., Patent Barristers, Solicitors, etc. Head office, Toronto. Offices in Montreal, Ottawa, Winnipeg, Vancouver and Washington, D.C., from whom all information may be readily obtained:—

S. Curran, poppet valves for internal combustion engines; H. A. Desparois, self-measuring pumps; G. Ashwood, showcases; C. H. Vessot and A. G. Mather, flax-pulling machines; A. Camirand, windmills; F. Dutcher, railway signal torpedoes; E. L. Knight, pilot-house propeller indicators; H. B. McElhinney, nail magazines.

Power generation and hydraulicking are accomplished with the same water at the Pioneer tin mine in Tasmania. The power-house is situated 300 feet above the mine, and generates electric current by the means of impulse turbines operating under a head of 189 pounds per square inch. During the six months ended December 31st, 1912, the mean power load was 482 kilowatts. The power is transmitted at 6,500 volts to the mine, and the water after leaving the turbines is conveyed 4¼ miles to a point 240 feet above the mine, where it is available for use in the pipe lines to the hydraulicking giants.—Power.

MEXICAN EAGLE ASPHALT

TRADE MARK

Delivered to meet the specifications of the American Society for Municipal Improvements, the Association for Standardizing Paving Specifications or any other standard specifications

Purchase MEXICAN EAGLE ASPHALT because:

1—It is more cementitious than other asphalts.

2—Water will not readily injure it.

3—Exposure to sun and air will not cause its deterioration.

4—It has great cohesive strength.

5—It is more ductile and flexible than other asphalts.

6—Shocks will not crack it. It is very malleable.

7—We will supply asphalt having the proper penetration for your needs.

8—It is best adapted to Canada's climate—will not mark in hot weather—nor are snow or ice likely to crack it.

9—It has over 99 per cent. bitumen. Purest on the market—therefore free from deleterious matter.

10—It is so constituted that it will not be injured by the heat necessarily applied to melt it for paving operations.

Samples, prices, analyses, etc., on request.

TRANSPORTATION BUILDING — MONTREAL

TENDERS CALLED FOR

TENDERS FOR A COMPLETE MECHANICAL FILTRATION PLANT.

BOILERS, STEAM TURBO-GENERATOR PLANT AND ALL APPURTENANCES.

Tenders will be received by registered post only addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on

Tuesday, January 20th, 1914,

for the installation of a complete Mechanical Filtration Plant, Boilers, Steam Turbo-generator Plant and all appurtenances at Toronto Island.

Specifications and Tender forms may be obtained upon application at the office of Mr. James Milne, Mechanical and Electrical Engineer, Department of Works, City Hall, Toronto.

Envelopes containing tenders must be plainly marked on the outside as to contents.

The usual conditions relating to tendering as prescribed by City by-law must be strictly complied with, or the tenders may be declared informal.

Tenderers shall submit with their tenders the names of two personal sureties approved by the City Treasurer, or, in lieu thereof, the bond of a guarantee company approved as aforesaid.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

City Hall, Toronto, November 25th, 1913.

DEPARTMENT OF RAILWAYS AND CANALS.

LACHINE CANAL.

NOTICE TO CONTRACTORS.

ROOFING ST. GABRIEL SHED No. 1.

Sealed tenders, addressed to the undersigned and endorsed "Tender for Roofing of St. Gabriel Shed No. 1, Ottawa Street, Lachine Canal," will be received at this office till **12 o'clock noon, Thursday, December 11th, 1913.**

Plans, specifications and form of contract to be entered into can be seen on or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer of the Quebec Canals, New Birks Building, Montreal, Que.

An accepted bank cheque on a chartered bank of Canada for the sum of $500.00 made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,

L. K. JONES,
Asst. Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 22nd November, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—51421.

TENDERS FOR ONE OVERHEAD HAND-OPERATED TRAVELLING CRANE.

DEPARTMENT OF WORKS.

Tender will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on **Tuesday, December 16th, 1913:—**

One Overhead Hand-operated Travelling Crane, having a working load of 40,000 pounds, for Main Pumping Station, foot of John Street.

Specification and Tender Form for the foregoing may be obtained upon application at Room 12, Pur. and Accounting Section of the Department of Works, City Hall, Toronto.

Envelopes containing tenders must be plainly marked on the outside as to contents.

The usual conditions relating to tendering, as prescribed by City by-law, must be strictly complied with, or the tenders may be declared informal.

Tenderers shall submit with their tenders the names of two personal sureties, approved by the City Treasurer, or in lieu thereof, the bond of a guarantee company approved as aforesaid.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman Board of Control.

City Hall, Toronto,
Nov. 26th, 1913.

TENDERS FOR ANNUAL SUPPLIES.

DEPARTMENT OF WORKS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on Tuesday, December 16th, 1913.

1. Asphalt (refined).
2. Paving Blocks (vitrified).
3. Granite or Stone Setts.
4. Treated Wood Blocks.
5. House Numbers.
6. Iron and Steel.
7. Special Castings.

Specifications and tender form for any of the foregoing may be obtained upon application at the Accounting and Purchasing Section of the Department of Works, Room 12, City Hall, Toronto. Envelopes containing tenders must be plainly marked on the outside as to contents. Conditions relating to tendering, as prescribed by city by-law, must be strictly complied with, or the tenders may be declared informal. Tenderers shall submit with their tenders the names of two personal sureties, approved by the City Treasurer, or in lieu thereof the bond of a guarantee company approved as aforesaid.

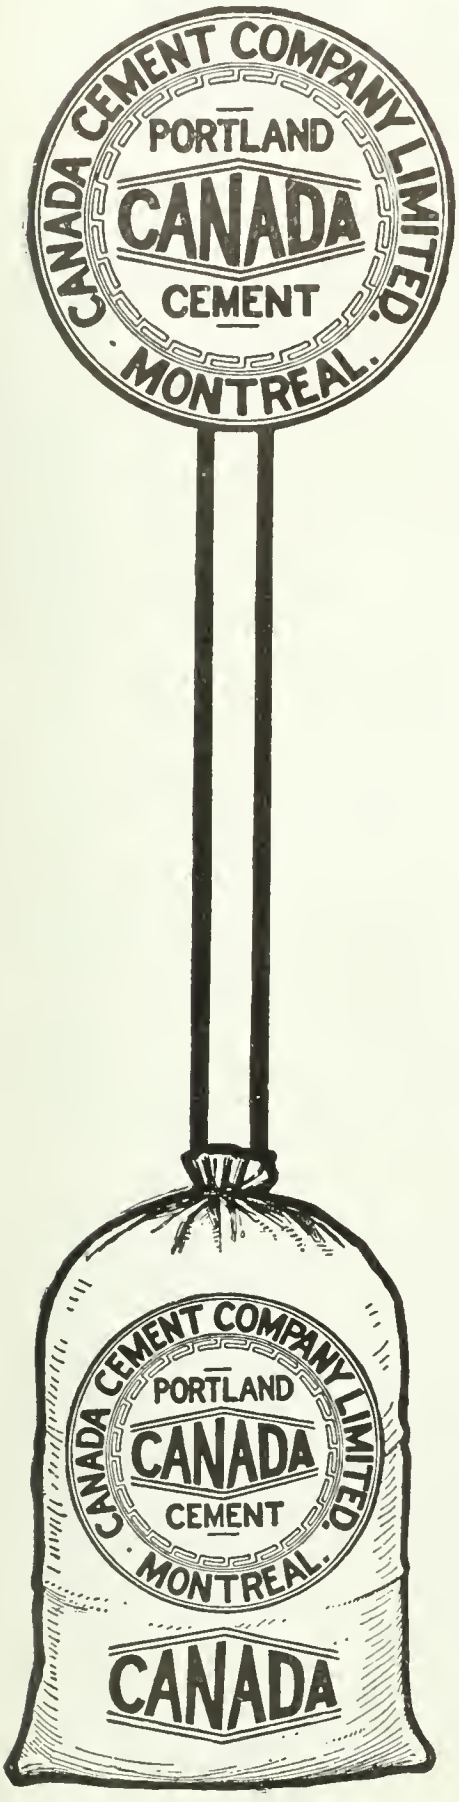
The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

City Hall, Toronto, December 1st, 1913.

(For further Tenders see page 90.)

PERMANENCE—



an ideal that is now attainable

THE superiority of concrete over all other materials for the building of permanent structures is now generally admitted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

Tenders Called For

TENDERS FOR LAYING 36-INCH AND 20-INCH WATER MAINS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, up to noon on Tuesday, December 16th, 1913, for the laying and jointing of a 36-inch water main from the High Level Pumping Station to West Toronto, in three separate contracts, and for the laying and jointing of a 20-inch water main in another contract.

Specifications and tender forms for the foregoing may be obtained upon application at the office of the Water Works Section, Department of Works, Room No. 9, City Hall, Toronto. Envelopes containing tenders must be plainly marked on the outside as to contents. Conditions relating to tendering as prescribed by City by-law, must be strictly complied with, or the tenders may be declared informal. Tenderers shall submit with their tenders the name of two personal sureties, approved by the City Treasurer, or in lieu thereof, the bond of a Guarantee Company, approved as aforesaid.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

City Hall, Toronto, November 26th, 1913.

(For further Tenders see page 88.)

It is stated that construction trains will be operated this winter on practically the whole line of the National Transcontinental Railway from Cochrane to Moncton. Contractors' trains have been serving the mills and colonists east and west of Cochrane for some little time. When the service is established eastward to Quebec, which is not far distant, now that the steel is practically all laid, it will be very advantageous to the public to use these construction trains, and at the same time their use over the new line will be an improvement to the track.

Positions Vacant

Advertisements under this heading two cents per word per insertion. Minimum charge fifty cents per insertion.

WANTED—Experienced electrical and mechanical draftsman. Address: Algoma Steel Corporation, Limited, Water Power Department, Sault Ste. Marie, Ont.

ASSISTANT ENGINEER—Good opportunity is offered a graduate, Mechanical or Electrical Engineer, to become connected as Assistant Engineer with an established Consulting, Engineering and Construction Corporation, based on co-operative plan. Main offices in Cleveland. Highest references and financial interest required. Contract with salary, commission and interest in business guaranteed. Answer Box 190, *Canadian Engineer*, Toronto.

Positions Wanted

Advertisements under this heading one cent per word per insertion. Minimum charge fifty cents per insertion.

GRADUATE SWISS CIVIL ENGINEER, with experience, wants appointment in Reinforced Concrete firm. Also seeks work for spare time. Preferred difficult calculations for reinforced concrete work, statically indeterminate systems. Please address Box 182, *Canadian Engineer*, Montreal.

STENOGRAPHER—Experienced in engineering correspondence, estimating and accounting, desires position, preferably as secretary. Gilt-edged references. Please address, Box 168, *The Canadian Engineer*, Toronto.

CIVIL ENGINEER in Riverdale wants to be initiated in Structural Steel design and detail by good Structural Steel draftsman living in Toronto. State fees and all particulars in first letter. Box 186, *Canadian Engineer*, Toronto.

MECHANICAL CONSTRUCTION engineer and draftsman, experienced designer and erector of mining plants, Marcus screens, coal-washing plants, and buildings, cost estimator and supervision, all kinds of steam engines, boilers, air machinery, etc., seeks position. References. Box 188, *Canadian Engineer*, Montreal.

WANTED.—Construction Foreman or Inspector wants position. First-class man on reinforced concrete structures, buildings, bridges, steel construction, mines, railways, etc. Good draughtsman and instrument man. Strictly sober. Box 192, *The Canadian Engineer*, Toronto.

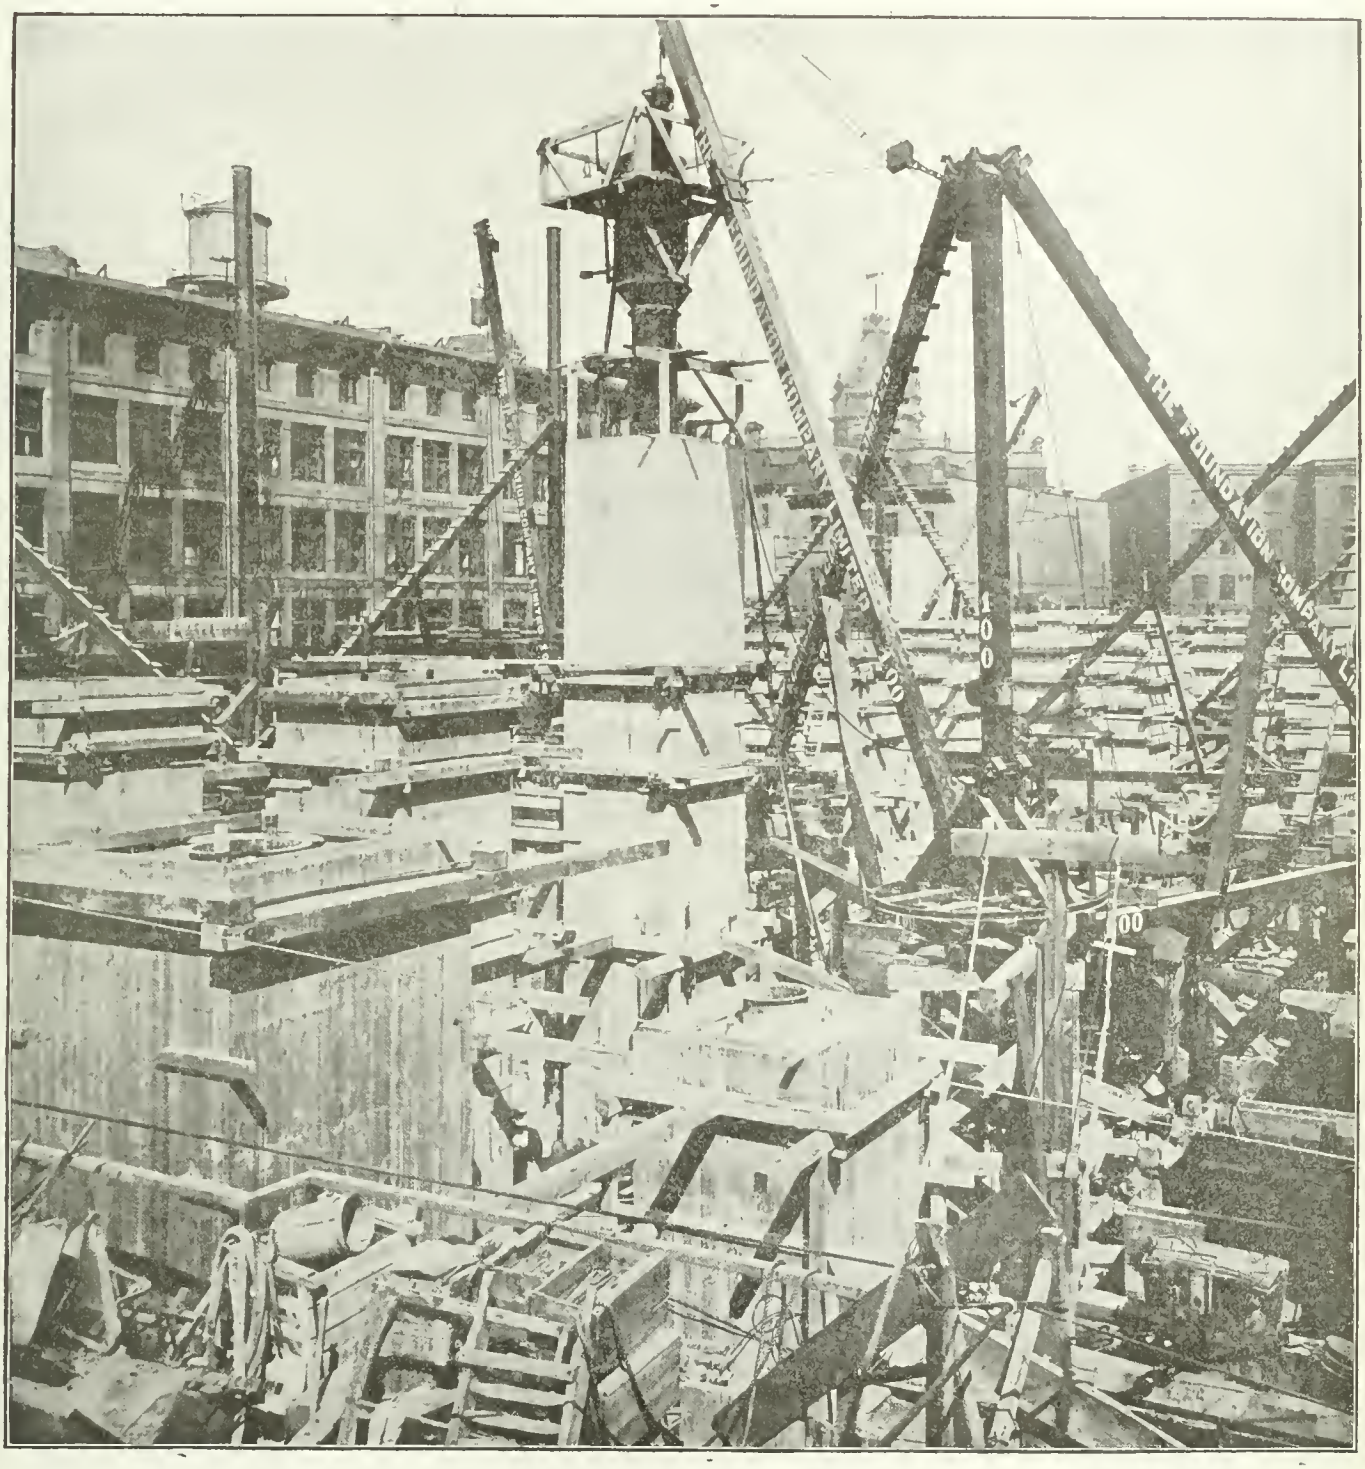
PATENT NOTICE—Anyone desiring to obtain the invention covered by Canadian patents No. 133,388, granted May 30th, 1911, for Surveying Instrument, and Patent No. 133,673, granted June 13th, 1911, for apparatus for Locating Forest Fires, to Daniel W. Adams, of Glendale Springs, North Carolina, U.S.A., may do so upon application to the undersigned, who are prepared to supply all reasonable demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh, & Smart, 53 Queen Street, Ottawa, Canada. Russel S. Smart, resident.

THE FOUNDATION COMPANY

MONTREAL LIMITED VANCOUVER



COMPRESSED AIR

Has helped to engineer some of the world's most famous Tunnels, Bridges and Skyscrapers. Under modern methods and organization it has become a speciality. The above shows the foundations for a new building in Montreal with caissons in various stages.

MARKET CONDITIONS

Montreal, December 1st, 1913.

Bar Iron and Steel—Trade is reported active. Bar iron, $2.05 per 100 pounds; best refined horseshoe, $2.30; forged iron $2.20; mild steel, $2.15; sleigh shoe steel, $2.15 for 1 x ⅜ base; tire steel, $2.25 for 1 x ⅜ base; toe caulk steel $3; machine steel, iron finish, $2.25.

Cement—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in. $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3.45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1-in., $3.05.

Explosives and Accessories—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4.30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $21.75 per ton; selected Summerlee, $21.25; soft Summerlee, $20.75 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19 to $19.50 per ton, on track.

Lath—See Lumber, etc.

Lumber, etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph poles: seven-inch top, cedar poles, 25-ft. poles, $2, each; 30 ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce 4-ft. x 1½ in., mill run, $3 to $3.25; pine, 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Pipe—Cast Iron—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe—Wrought and Galvanized—Demand is fair and the market steady:—¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent. off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. off for galvanized: 3½-inch $95 4-inch, $1.08.

Toronto, December 3rd, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes—Orders continue active. Lap-welded, steel, 1¼-inch, 10c. 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto 60 cents.

Cement—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks, 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps—75c. and $1 per 100; case lots, 5,000, 20 per cent. off.

Dynamite—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents per pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cents.

Fuses—Electric Blasting—Double strength, $3.50 per hundred, advance 5c. per hundred for each 2 in. wire additional. Single strength, $3 per hundred, advance 5c. per hundred for each 2-in. wire additional.

Iron Chain—¼-inch, $5.75; 5-16-inch, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanized Pipe, ¼-inch, $2.86; ⅜-inch, $2.86; ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead—Firmer, $5.25 to $5.50.

Pig Iron—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green $8, with a prospect of advance. Dealers are fairly busy.

Sand—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0 25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. traps	2.00	3.20	6.50	15.00	....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes 9 inches and under, or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels—Active—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 lbs. Extra for smaller sizes of angles and tees.

Sheet Copper—22c. per lb.

Sheet Steel—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized—Apollo Brand—Sheets, 6 or 8 feet long, 30 or 36 inches wide: 10-gauge, $3; 12-14-gauge, $3; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 lbs. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel—Jowett's special pink label, 10½c. Cammel-Laird, 16c, "H.R.D." high speed tool steel, 65c.

Tank Plates—3-16 inch, $2.40 per 100 lbs.

Zinc—Spelter—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, December 2nd, 1913.

Anvils—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¼ to 10¾c., anvil and vise combined, each $5.50.

Bar Iron—$2.50 base.

Bars—Crow, $4.50 per 100 pounds.

Beams and Channels—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41.50, 118, 119, 172, 132, 145, 176.

Brick—Kiln run per M, $13; sewer pipe per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland—$2.40 to $2.50 per barrel.

Chain—Coil, 3 16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜ $5; 7-16, $4.75; ½, $4.50, 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper—Tinned, boiler, 26½c., planished, 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent. discount.

Dynamite—$11 to $13 per case.

Galvanized Iron—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20 $4; 18 $3.95; 16, $3.90. Queen's Head, 28, $4.90; 26, $4.70; 24, $4.80 22, $4.20; 20, $4.10 per cw

Iron—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26 gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American $5.15; Fleur de Lis 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe—Iron, Black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.50; 1½-inch, $9.35, 2-inch, $12.50; galvanized—¼-inch $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled—3-16-in., $3.35 base; machinery, $3 base; share: $4.50 base; share crucible, $5.50; cast share steel, $7.50; tee caulk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel—8½ to 15c. per pound.

A weekly paper for engineers and engineering-contractors

THE DESIGN OF MEDIUM SIZED COAL GAS PLANTS

THE CONDITIONS GOVERNING THE SELECTION OF GAS PLANT—DESCRIPTION OF DESIGN AND OPERATION OF THE COAL GAS PLANT AT NORTH YAKIMA, WASH.

By GORDON KRIBS,
Assistant Chief Engineer, Texas Power and Light Co., Dallas, Texas.

GAS plants for supplying towns and cities with illuminating gas may be divided into three classes according to the type of gas they are designed to manufacture. (1) Coal gas plants; (2) water gas plants, and (3) oil gas plants. In deciding on the type of gas plant to be used in any particular locality, several points should be considered, the main ones being as follows:—

1. Location as to source of fuel and gas-making materials.
2. Cost to manufacture.
3. Physical and chemical properties of gas desired.
4. Market for residuals.
5. Likelihood of competition with natural gas.

Let us examine these points in the order in which they come.

Raw Materials.—The location of the source of fuel supply and other raw material and the cost of getting same to the point where they are to be used has an important bearing on the type of gas plant to be used, as it is of prime importance in figuring the cost of manufacture.

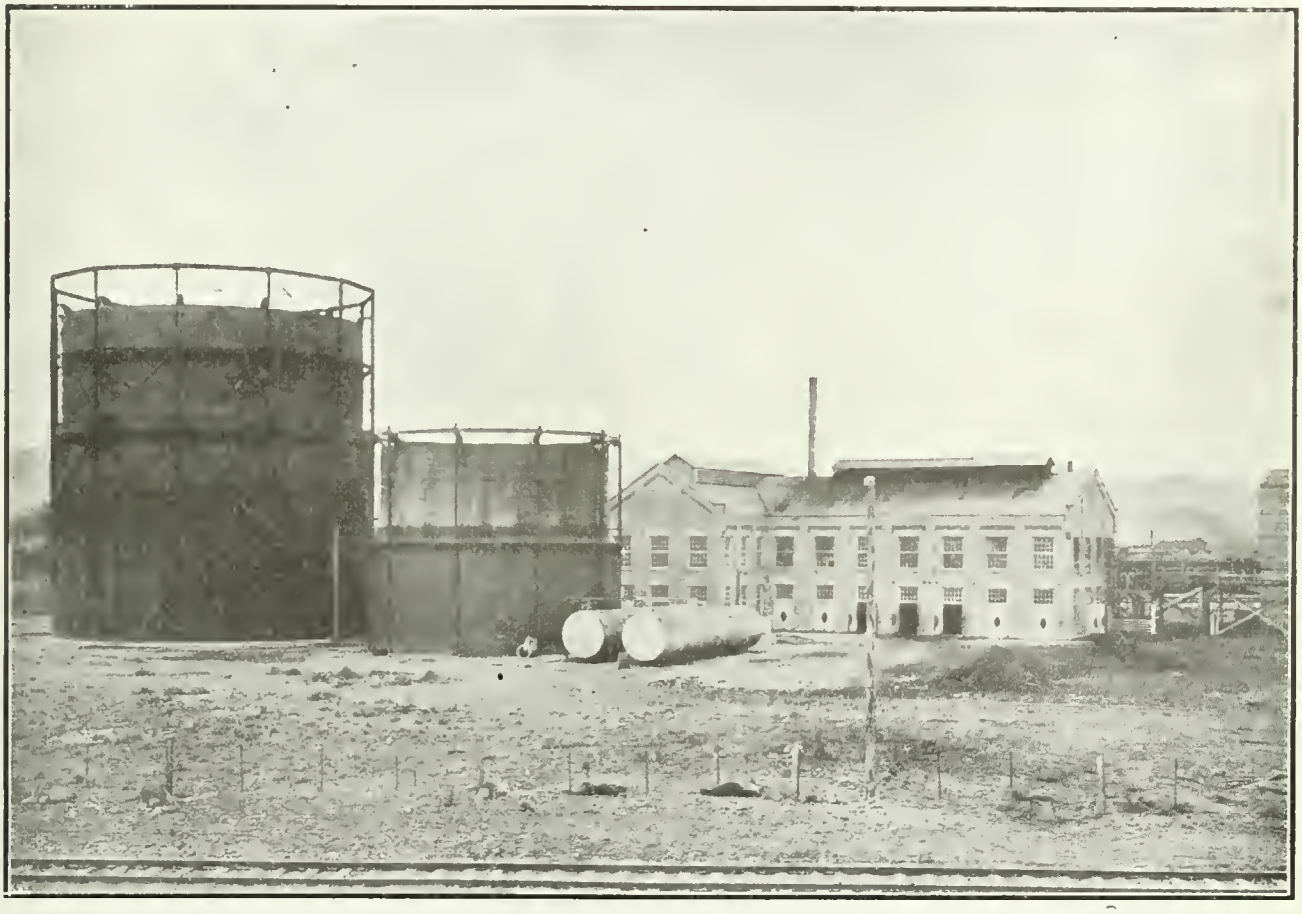

Fig. 1.—Gas Plant of Pacific Power and Light Company at North Yakima, Wash.

For example, at North Yakima, Wash., it was decided to install a coal gas plant for the reason that good gas coal can be procured in the mountains at Rosslyn, about sixty miles away. The haul is short and down

grade, and the freight rate low, making the price of raw material correspondingly low. Oil can be had, but as it must come from the California oil fields, the freight rates are high; it has to be transhipped from steamer to cars and the source of supply could not be guaranteed as constant without installing immense storage tanks. Hence, the cost of both oil and water gas would be excessive.

At Portland, Oregon, however, the gas plant installed is of the oil gas type. Oil can be brought from California to the plant in tank steamers and unloaded directly from the steamer into the storage tanks at the plant. Hence oil is comparatively cheap and under the conditions the oil gas type of plant resulted in the lowest cost of manufacture.

At Paris, Texas, however, coke can be procured at a reasonable cost, while oil is also procured at a fair price, and it has been found least expensive to use water gas in the plants in this district than any other. Hence most of the plants in Northern Texas are either water gas or a combination of water and coal gas.

Cost to Manufacture.—The cost to manufacture the various kinds of gas varies in different localities. The following table gives the cost to manufacture coal and oil gas in various localities on the Pacific Coast for October, 1910. These are all medium and small sized plants and, of course, this cost can be somewhat reduced in plants of larger capacity.

Cost of Gas Manufacture per M. Feet, October, 1910.

Town.	Walla Walla.	Pendleton.	Lewiston.	North Yakima.	*Astoria.	Salem.
Production cost	.62	.38	.70	.54	.54	.70
Transmission and distribution	.09	.08	.05	.12	.06	.35
Commercial expenses	.09	.14	.11	.07	.01	.06

Oil per bbl.	....	....	....	....	$1.05	.....

*Oil gas plants.

Physical and Chemical Properties of Gas Desired.—The principal characteristics of a gas, which are of interest to the consumer, are as follows:—

1. Candle-power.
2. Heat units or B.t.u.'s per cu. ft.
3. Amount of injurious or objectionable constituents in the gas.

The lighting customer is interested, of course, in getting as much light from his burner as possible, and hence in some franchises granted gas companies by the municipality a certain candle-power is stipulated, and to meet this requires care in the manufacture and it may also be a deciding point in the choice of the type of gas plant to be used. The standard for measuring candle-power is a flame burning at the rate of 5 c.f. per hour, the gas being measured at 60 degrees Fahr. and 30″ barometer, or corrected to this. This flame is compared with a standard sperm candle which weighs six to the pound and burns at the rate of from 114 to 126 grains per hour.

The heating customer is much more interested in the number of B.t.u.'s per 1,000 cu. ft. than he is in the candle-power of his gas, and hence franchises are sometimes drawn up stating the limiting heat value of the gas in B.t.u.'s, below which the gas company must not allow it to fall. This also is of very great importance in deciding what type of gas plant will be used. The average heating quality per cu. ft. of various gases is given in the following table:

Pennsylvania natural gas	1,145
Ohio and Indiana natural gas	1,095
Kansas natural gas	1,100
Average coal gas	755
Texas (Petrolia Field) natural gas	630
Average water gas	350
Average bituminous producer gas	155

The presence of injurious and objectionable constituents in the gas is usually entirely the fault of the gas company, as by means of the proper condensing, purifying or reheating apparatus, all objectionable impurities may be removed. Among the more important impurities in crude gas may be mentioned, ammonia, hydrogen-sulphide, carbon-dioxide, carbon-bisulphide, cyanogen, tar, carbon, and naphthalene. The market for residuals has considerable influence on the net cost of manufacture of the gas. Coal gas produces:—

1. Ammonia liquor—and if the plant is large enough to warrant the installation of a still to concentrate the liquor it is a source of considerable revenue.

2. Coal tar—a coal gas plant produces a considerable amount of heavy, dense tar which is in great demand for roofing and as an ingredient in preservative paints and a gas plant can usually dispose of their entire output very readily.

3. Coke—a coal gas plant produces a large amount of coke, the quality, of course, depending on the time that the coal has been in the retorts. The kind of coal used also influences the quality of the coke to a large extent. While some coke can be used in the benches and boilers as fuel, yet only a small proportion can be used up in that way, and the remainder has to be sold or it will accumulate very fast. Usually the breeze and smaller pieces can be used as plant fuel, leaving the best of the coke for sale, and the market is generally very good. It sometimes happens that a company operating several coal gas plants can erect a water gas plant at some convenient point in order to utilize the coke from the coal gas plants.

Water gas produces a very light and watery tar, which is not in such demand as coal tar. It is, however, usually possible to find a market for same, and failing in that it can be sprayed under the boilers and used as fuel, although even then it makes a very indifferent fuel.

Oil gas produces large quantities of lamp black, a finely divided and almost pure carbon. In small plants

this may be separated from the plant liquor and dried and used under the boilers. In large plants the carbon may be pressed into briquettes which may be sold as a substitute for coal. The Portland Gas and Coke Company, of Portland, Oregon, handle it this way and find ready sale for all they make. Unless the plant is large, however, it does not pay to do this, as the machinery for handling same is expensive.

All these points regarding residuals should be carefully gone into before deciding on the type of plant to be installed, as they have a marked influence on the net cost of manufacture.

It is the purpose of this paper to consider only the first-mentioned type of plant, namely, the coal gas plant, and in order to facilitate the description of the design and operation of a coal gas plant, it is well to select an example, and hence the description which follows applies to the North Yakima plant of the Pacific Power and Light Company, situated in North Yakima, Washington.

In connection with the following description, reference may be had to Figs. 1, 2 and 3. Fig. 1 is a general plan of the coal gas plant, the building in dotted lines being the old plant which was displaced by the new one. Fig. 2 is a detailed layout of the main building, consisting of the retort room, exhauster room and condenser room. Fig. 3 shows elevations and sections of the main building showing type of building used. The buildings are two in number, built of red brick. The larger is the retort house and the smaller the meter house.

The main building is divided into four rooms, namely, the bench or retort house containing the benches and boiler; the condenser room containing the condenser; tar extractor, etc.; the exhauster room containing the exhausters and compressor, and above the exhauster room is arranged a wash room for the employees, containing toilet, shower baths, bath tub and lockers. The meter house contains the station meter and valves for controlling the operation of the holders. The roof of the retort house consists of steel trusses of the Fink type supporting the roofing material which is of asbestos protected metal. The meter house has a concrete roof. The storage holders are two in number, one being a single lift holding 43,000 cu. ft. capacity and the larger one a double lift of 150,000 cu. ft.

Coal for the plant is brought in by rail and stored in an elevated coal storage bin. From this bin the coal is handled by means of a one-ton car fitted with roller bearings and run on an industrial track of 26-lb. rails, supported on pressed steel ties. The track is so arranged that the car may be run over a track scales and an accurate account is kept of the amount of coal used in the plant. It is then run in front of the benches and the stoker shovels the coal directly from the car into the retorts. There are three benches of 6's manufactured by the La Clede-Christy Company installed at the present time with provision for a fourth. They are of the half depth, rear clinkering, through retort, semi-regenerative type, each bench having 6 retorts 26" x 15" inside by 11 feet long. The coal is shoveled in the front end, and when carbonized, is removed by a special hand-operated coke pusher supplied by Isbell Porter Company, Newark, N.J., and which removes the coke in a few seconds, being

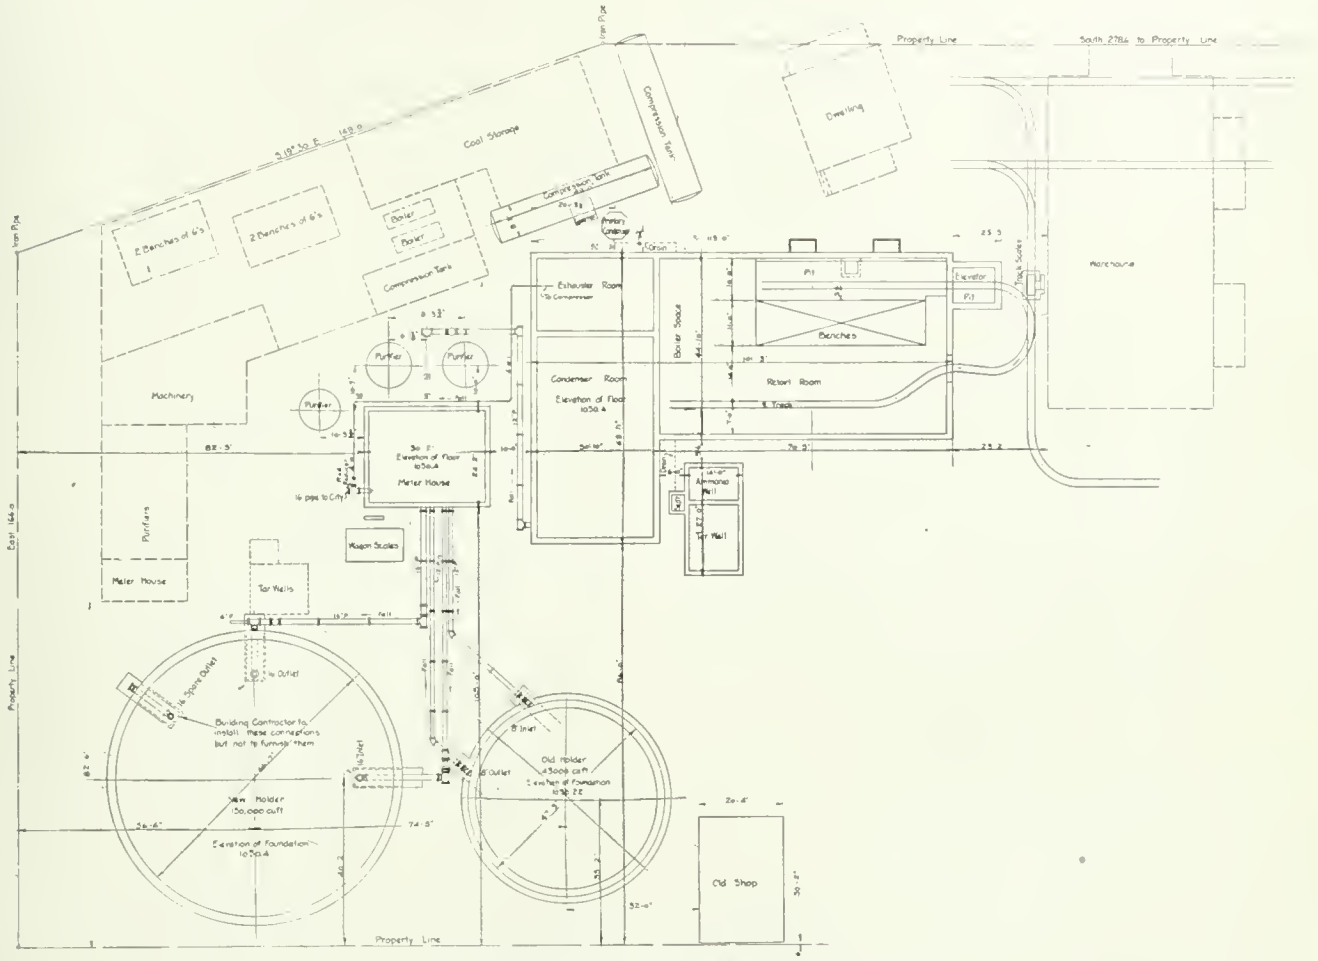

Fig. 2.—General Plan, North Yakima Coal Gas Plant.

much ahead of the old method of hand-raking. The coke is removed by pushing it out the rear end of the retort and falls into steel hoppers in the rear of the benches, where it is quenched with water and dropped into a small industrial car in the pit. This car is similar to coal car, with the exception that it is lined with asbestos. It is elevated to the level of the coke runway by means of a 2-ton platform sidewalk elevator which is motor-driven.

Coke is used in the benches for fuel. About three hundred pounds of coal is charged per retort and is carbonized from twelve to eighteen hours. The capacity of each bench is from 50,000 to 75,000 cu. ft. of gas per day according to the quality of coal used and heats run. The capacity can even be run above this by increasing the heat, but it is detrimental to the life of the retort.

When coal is roasted in an airtight retort at about 1,200 degrees Fahr., crude coal gas is given off mixed with tar and ammonia and other impurities, and if the heats are not proper, considerable naphthalene and carbon will also be formed. One ton (2,000 lbs.) of average coal will give 9,800 cu. ft. of 14 to 15 c.p. gas, 1,300 lbs. of coke, 12.5 gallons of tar, 27 gallons of 6 oz. ammonia liquor and 1 lb. of retort carbon. Naphthalene is a very troublesome substance in that it is normally a solid but is capable of being transported long distances in the form of vapor by coal gas. When, however, the temperature of the gas is reduced to such an extent that it becomes saturated with the vapor the naphthalene crystallizes out in the form of flakey white crystals which occupy a large volume and if deposited in large quantities will stop up mains and services. Carbon formed in the retorts is deposited in the stand-pipes, causing stoppages and other operating worries. After forming in the retort the gas is conveyed through the stand-pipes to the hydraulic main which acts as a seal to the retorts when they are open and prevents the return of the gas. It collects the heavier tars which should be drained off periodically and the water dissolves a portion of the ammonia but, being hot, the percentage is small.

Nearly all the ammonia present in crude coal gas is in the "free" state, i.e., it can be driven off by merely heating; only from 5 to 15% being fixed. Coal gas contains approximately 350 grains of ammonia per 100 cu. ft. At the outlet of the condensers, this is reduced to 250 grains and at the outlet of the washers and scrubbers this amount has been reduced to 1½ grains.

The gas leaves the hydraulic main varying in temperature from 140 degrees to 130 Fahr., and is conveyed by means of the 12" foul main to the primary or air condenser, which is situated just outside the exhauster room. The gas should be approximately 110 degrees Fahr., in order to be able to extract the tar from it satisfactorily and it is the duty of the primary condenser to reduce the gas to this temperature before it reaches the tar extractor. The primary condenser is 6' in diameter by 20' high, made of ¼" steel shell, has 61 tubes 3" x 17' and if fitted with a stack 24" diameter. by 14' high, which induces a natural draught through the apparatus, the draft being controlled by means of a stack damper. A portion of the tar and ammonia are deposited in the primary condenser and are drained by means of a suitable drain to the tar and ammonia separator and tar well.

The next piece of apparatus is the exhausters, which are two in number. They are of the P. H. & F. M. Roots type, known as a No. 4, and each have a capacity of 17,700 cu. ft. per hour per 100 revolutions. One exhauster is driven by a 5" x 7" vertical engine direct connected while the other is motor-driven, being belted to a 5-h.p. variable speed A.C. motor. The speed of the engine-driven unit is kept proportional to the amount of gas being made by means of an automatic governor. The speed of the motor-driven exhauster is hand-governed. The function of the exhauster is to take the gas from the hydraulic main on top of the benches and force it through the various purifying devices and into the holders against the holder pressure. The only pressure which the gas in the retorts is under is due to the amount of seal of the dip pipes which varies from 1" to 2" of water, preferably 1". By the use of the exhauster the amount of carbon deposit in the retort is lessened; the loss due to leakage is very much less, and the amount of gas obtained from a given quantity of coal greater.

From the exhauster the gas is forced through the tar extractor, and in this case a 12" P. & A. tar extractor was used. This piece of apparatus is most efficient and extracts practically all the tar from the gas. The principle of operation of a P. & A. tar extractor is as follows: The gas to be purified is forced through a series of small holes forming jets which impinge against a flat surface opposite. Tar is conveyed by the cool gas in the shape of small bubbles, and when the gas strikes the flat surface these bubbles attach themselves to it and drip down to a reservoir from which a pipe leads to the tar drain and then to tar well. The reason for locating the tar extractor in this order is due to the fact that the heavier tars have when cold, the property of absorbing the lighter hydrocarbons which are very efficient as light givers, thus destroying to some extent the value of the gas as an illuminant.

The next piece of apparatus is the secondary or water condenser, which consists of a steel shell 5" diameter by 19' high, made of ¼" steel boiler plate and contains 61 tubes 3" x 16' long. The gas circulates around the tubes and the cooling water through them, the gas entering at a temperature of 90 to 100 degrees Fahr., and being cooled to a temperature of 60 to 70 degrees Fahr., at which temperature it is ready for the scrubber. When the gas reaches the secondary condenser it has been relieved of all but a small percentage of the tar it contained. It, however, still contains many other impurities, a considerable amount of water vapor, and ammonia compounds. The water vapor and some of the ammonia is condensed and collects in the bottom of the condenser, from which the solution is taken by means of a special syphon drain 3" in diameter. The condensers in the North Yakima plant were installed in duplicate and the piping so arranged that either of the condensers could be used at a time or both in parallel. It should be noted that cooling the gas too quickly is very detrimental, as it reduces the candle-power by condensing some of the most effective light-giving hydrocarbons.

The gas next passes on to the scrubbers which, in the case of the plant described, consisted of two units arranged so as to be used singly or in parallel, each 6' diameter by 19' high with 10" inlet and outlet nozzles and five 13" x 18" manholes. The inside of the shell is filled with wooden trays composed of small slats of wood, over which a small stream of water is kept flowing, just enough water being admitted to keep the slats wet. The gas is admitted at the bottom of the shell and in passing up between the slats is broken up into small streams coming into intimate contact with the water passing down. The cold water meeting the gas previously cooled in the secondary condenser readily absorbs the ammonia remain-

ing in the gas. It also absorbs and combines with a portion of the CO_2, which is very desirable, as one volume of this gas in 100 of illuminating gas will reduce the candle-power 5%. The liquor is collected in the bottom of the scrubber and is drained off by means of a special syphon connection which seals the apparatus and prevents the escape of the gas, at the same time allowing the liquor to escape. The liquor flowing from the condenser and scrubber is conveyed by means of a 3" main to the tar and liquor separator. The gas then passes out of the condenser by means of a 12" main and on to the purifiers, which are located just outside the condenser room.

It will be noted that the exhausters are in a room by themselves as are also the condensers and scrubbers, and these can only be reached from the retort room by going outside, there being no inner passageway. This arrangement reduces the risk of explosion due to leaking gas making an explosive mixture.

The purifiers are situated outside and consist of three steel boiler-plate boxes 11" in diameter and 12' high, the sides and bottom plates being ¼" and the top plates 3/16". Each box is equipped with two layers of oxide trays and a ½-ton duplex chain hoist for lifting cover. They are interconnected by means of valves and piping so that as flexible arrangement as possible was secured. The boxes were arranged so that the direction of the flow could be reversed in all the boxes and any two could be placed in series or any two in parallel with the third in series. The advantage of reversing the flow lies in the fact that when one side of the bed of oxide becomes clogged the other side may be used, thus extending the periods between revivifying. The oxide used in this particular case was made up by the following formula, and gave good satisfaction: 6 bbls. pine shavings, ½ bbl. lime, ½ bbl. copperas.

The principal impurities in the gas when it leaves the scrubbers are hydrogen sulphide, carbon dioxide and carbon bisulphide. Lime is very active in the removal of CO_2 and H_2S and after absorbing the H_2S it also requires the property of absorbing carbon bisulphide. It is the office of the purifiers to eliminate these objectionable compounds from the gas and the efficiency depends altogether

Summary of Costs—North Yakima Coal Gas Plant.

No.	Article.	Quantity.	—Unit— Used.	Cost.	Total.	Remarks.
I.	Buildings	204,755	C.F.	.10¼	$21,023.75	$21,959.72 Grand total
II.	Wrecking old buildings.				935.97	On contract
						Total, $23,306.23
III.	Miscellaneous structures:					
	(a) Tar well				746.11	3,300 C.F. capacity.
	(b) Industrial track (installed)				923.59	860 ft. 20-lb. track and pressed steel ties.
	(c) Gas holder			.14		
	(installed)	150,000	C.F.	7.00	21,636.53	150,000 C.F. 305,166 lbs.
						Total, $37,600.86
IV.	Machinery & equipment:					
	(a) Benches (erected)	4 benches	2787.12		11,148.50	3 benches of 6's filled and one empty,
	(b) Gas machinery ...				20,145.77	capacity 60,000 C.F. each per 24 hours.
	1. Gas treating apparatus					Includes 2 condensers, 2 exhausters, 2 scrubbers, tar and ammonia separator. Works piping, yard piping, station meter, 2 purifiers, all erected on purchasers foundations (by contract).
	2. Compressors				344.17	Moving and changing to motor-drive.
	3. Boiler, 75 h.p.....				1,314.16	
	4. Boiler piping—exhaust head, etc.				101.35	4" Burt exhaust head and piping.
	5. Coke pusker				1,083.40	Hand-operated discharge machine, including runway.
	6. Coke quenching chutes				1,264.08	8 McDonald & Mann coke-quenching chutes and motor-operated sump pump.
	7. Coke elevator				1,371.19	Two-ton motor-operated sidewalk elevator.
	8. Coke and coal cars	4	cars	$143.60	574.40	
	9. Miscellaneous ...				341.74	Includes labor moving compression tanks, cost of 3 ton track scales, etc.
V.	Overhead charges	14.5%			11,997.03	Includes 10% engineering fee, interest during construction, storeroom expense, superintendence, timekeeping, etc.
	Total.....				$94,951.74	Daily capacity 180,000 C.F. or 52c. per C.F. daily generating Capacity.

on the size of the purifiers, and the condition of the oxide. After the oxide has been used for some time, it loses its efficiency as an oxidizer and is revivified by being removed and spread out in a thin layer on a flat surface and exposed to the air, being turned over repeatedly so as to expose every part of it. When thoroughly revivified it is ready for use again. A large concrete slab is usually provided for treating the oxide. A small shed is also provided for an oxide storage.

From the purifiers the gas passes into the storage holders, which in this case are two in number, the old holder of 43,000 cu. ft. and one new one of 150,000 cu. ft. capacity, having a total weight of 305,166 pounds. The small holder is a single lift type with a steel containing tank, while the new holder is of the double lift type. Each holder is supplied with drip pots to collect tar and gas liquor, the C.I. mains being laid so as to drain towards the holders. All gas house piping is of cast iron, mostly bell and spigot leaded. All fittings are standard gas fittings, reducers being eccentric and all mains being laid so as to convey gas liquor and tar to some point where it can be readily removed to a drip pot or seal. All elbows are provided with hand holes in order that the pipes may be rodded in case they become clogged. Tees are used in the piping instead of ells for the same reason and the tar drains are made as straight and short as possible, allowing as much fall as convenient under the conditions. In passing from the holder on its way to the distributing system the gas is made to flow through the station meter. This meter is of the wet type, 72″ x 72″, and is supplied with a Hinnman drum. The capacity of the meter is 500,000 cu. ft. per day with a loss of 1″ pressure. The inlet and outlet pipes are 10″ and the meter is furnished with a by-pass in order that it may be taken out of commission without seriously interfering with the delivery of gas.

The system of distribution used in North Yakima is known as the high pressure system. The gas is drawn from the holders through the station meter and compressed into two compression tanks 8′ 2″ x 10′ to 40 lbs. pressure by means of an Ingersoll Rand 9″ x 11″ steam-driven compressor running at 160 r.p.m. A 2″ high-pressure main conveys the gas to the centres of distribution in the city where district regulators reduce it to the standard 3″ pressure for commercial use.

A 75-h.p. boiler supplies this compressor as well as the gas exhauster with steam. The boiler also supplies hot water to the holder cup in winter, so as to prevent freezing, and is also used to heat the building during the cold weather and supply hot water to the men's wash-room.

A table showing the cost of the above plant is shown on the previous page.

It is announced from Zanzibar, East Africa, that the building of the railway through German East Africa is going ahead successfully, and if the hopes of the promoters are realized, will be opened for public traffic early in 1914. The line has been completed to within 210 miles west of Tabota, whilst the earthworks has been carried to within 30 miles of Ujiji. No native is allowed to leave the Belgian Congo or German East Africa without special permission, and the regulations which govern them are strictly enforced. Even the Governor is not allowed to grant this permission without a contract from the recruiters of native labor that the men shall be returned to their own country at the expiration of the contract.

SOME TESTS OF CAKED CEMENT.

The following tests of eight samples of caked cement were made at the Kansas City Testing Laboratory, Kansas City, Mo. The object of the tests was to determine the effect of caking on the tensile strength of cement. The tests were made on neat cement and on 1:3 briquettes. The results of the tests are given in Table I.

Table I.—Results of Tests of Briquettes Made From Caked Cement.

	Neat cement			1 cem.: 3 sand.	
Ref No.	24 hrs.	7 days.	28 days.	7 days.	28 days.
1	259	691	811	250	317
2	304	778	861	242	391
3	215	646	807	318	404
4	185	545	708	165	265
5	203	510	703	255	325
6	135	643	865	335	443
7	115	505	698	190	304
8	190	650	822	230	390

The breaking strengths in pounds per square inch at various ages are given in the table. Some of the cement used was badly caked. This is especially true of specimen No. 4, as this cement had been stored in an old basement against a porous sandstone wall.

Although these tests show a wide variation, most of them developed sufficient strength to pass standard specifications. They do not show as definite an increase of strength as should be given by fresh cement, but this may in part be due to the lumps not being uniformly pulverized. In reporting these tests it was stated that "while it is safe to use caked cement, it must be observed that unless the cement is again perfectly powdered, any remaining lumps of cement will not have any bonding effect, and more cement in sufficient quantities must be used to compensate for any undisintegrated lumps that may remain."

When practically all of the cement was imported from Europe, it was not uncommon to find that the cement in some of the barrels was sufficiently hardened to remain in position after the staves were knocked off. In such cases the cement was not rejected, but was powdered and used with satisfactory results. It is known by testers of cement that Portland cement which has caked and has then been powdered and used does not set so rapidly nor does it acquire its maximum strength so quickly as does cement which has never caked; yet testers have found that the strength of such material is practically unimpaired and that it will pass the requirements of specifications. Of course, the safe thing to do is to use only fresh cement, but to reject all cement which contains lumps may result in a very considerable loss. If cement which contains some lumps is used, care should be taken to thoroughly pulverize the lumps before using it.

Mr. H. C. Cooke, of the Geological Survey of Canada, has completed researches on Vancouver Island, and asserts that as a result of his investigations, which have been carried on since May of this year, he is able to state authoritatively that there are great prospects of copper development in certain sections, notably in the vicinity of Sooke and also of Ladysmith. It is anticipated that his report, while pregnant with valuable geological data, will attach particular significance to the copper-bearing regions of the Island he has come in contact with.

PAINTING STRUCTURAL STEEL.

A PAPER to be presented to the American Society of Civil Engineers on January 7th next by A. H. Sabin, A. M. Am. Soc. C.E., outlines the situation as it obtains at present in the painting of structural steel. The corrosion of structural metal by atmospheric and other natural causes is a subject which has long been of importance to the engineer. A few years ago, the greatly increased use of concrete structures aroused the hope that danger from such corrosion would be much reduced; but unarmored steel seems to be used as much as ever. Concrete has not taken its place, but has made an entirely distinct place for itself. Much has been written, and much has been done, relative to the protection of steel; but improvement has been slow, progress being made step by step.

Some years ago, Mr. G. W. Thompson attempted to classify pigments, as to their relation with iron, by suspending them in water and immersing pieces of iron or steel in these mixtures. The results were somewhat surprising; some of the pigments which common experience approved, seemed to increase corrosion in this condition, and others, known to be useless in protective paints, seemed to be much better for preventing it. Lampblack, for instance, was the worst in provoking corrosion, and white zinc or pulverized chalk prevented it. This was probably due to the fact that lampblack contains, condensed on the surface of its particles, considerable carbonic acid, which is the most generally active agent in the corrosion of iron, and white zinc and chalk are basic substances by which iron is not rusted; however, the carbonic acid in lampblack is displaced by grinding in oil, and the well-known lack of durability in paints made of white zinc and chalk prevents their good qualities from coming into action.

So great is the need of more knowledge as to the value of pigments in paints, and their mode of action, that nothing promising new information is neglected. A committee of five chemists from different parts of the United States, with the approval of the Society for Testing Materials, made a series of tests of the principal pigments, and of some other substances, on steel immersed in water; and, as was to be expected, arrived at substantially concordant results. These results, as has been stated, were of no value from the standpoint of the paint-maker, being inconsistent with the known value of the pigments when ground in oil or varnish. When the report was published, however, the pigments were classified, according to their water value, into three groups, namely, inhibitors, indeterminates, and stimulators. This was the origin of the use of these now well-known words in paint terminology. It was expressly stated in the report that this was a classification as regards water only; but the names were so convenient and so tempting that those not familiar with the subject and also many who saw their value for advertising purposes (two quite distinct classes), put them into common use to classify pigments in oil. It is obvious that any classification of pigments in oil should be based on their behavior in oil, and if, as must be conceded, this is radically different from water tests, the latter should not be regarded. All this investigation began some years ago; meanwhile numerous young men, mostly students working under the supervision of their teachers, have made brief and generally inconclusive studies of paints, and almost without exception have used these indefinite terms, inhibitors and stimulators. Patents have even been taken out—which, in the writer's opinion, are not only worthless but invalid—covering the use of old and well-known pigments. What is worse, every maker of a paint nostrum assures his hearers or readers that his particular paint absolutely inhibits rust, and that everything else stimulates it. This is the whole history of this jargon about inhibition and stimulation; it never had any particular value to the consumer, and it is generally used to mislead him.

It is obvious that in a good paint the pigment particles are enveloped in a film of oil; they do not come in contact with the iron; if they did, the paint would peel off, for no dry pigment adheres well to metal. It is as true to-day as it has been in the past that steel rusts because air and moisture act on it; and paints are used to keep air and moisture from it. They do not inhibit rusting, except as they inhibit the cause of it.

The important practical question is whether paints have been or can be improved as to being non-porous and durable. This is essentially dependent on the relation between the pigment and the oil. As to the true nature of this relation, very little is known; but something is known about its visible manifestations. It is known, for instance, that 1 lb. of dry red lead mixed with ¼ lb. of oil makes a paint of ordinary consistency, and 1 lb. of dry lampblack requires at least 6 or 8 lbs. of oil, say, thirty times as much, or making allowance for difference in density, six times as much, as the red lead. Similarly, 1 lb. of white zinc takes twice as much oil to make a paint as 1 lb. of white lead; and white lead takes nearly twice as much as red lead. These are things we know; but we have no idea why they are so. Again, red lead, which is an oxide of lead, makes an excellent paint for iron; oxide of iron is neither very good nor very bad; oxide of manganese is bad. Our knowledge of paints is as yet largely empirical; chemists dislike to admit this, for like everybody else, they hate to confess that there is anything they do not know, and thus when a new theory is offered some of them make a great rejoicing over it without first finding out whether or not it agrees with the facts. Where we are gaining is in more general appreciation of the value of the proper application of paint, better preparation of surface, more confidence in good paint rightly used, and in the better preparation of paint materials. For instance, in the older books, and until about twenty years ago, we find analyses of red lead showing as low as 55 per cent. of true red lead, with 45 per cent. of litharge. Red lead is made from litharge, and the presence of the latter is not a sign of adulteration, but of incomplete conversion. At the same time other samples showed as high as 80 per cent. of true red lead. As is well known, there was much difference of opinion in those days as to the value of red lead as a paint for iron; though most users liked it, some thought it poor stuff. It is now known that its value depends on the quantity of red lead it contains. Coarse red lead always contains litharge, because the litharge in the middle of a large particle is never oxidized. It was observed that the finer the red lead, the better it was, and so a demand arose which forced the manufacturers to make higher grades; now they are grinding their litharge to an impalpable powder before roasting it, with the result that 94 per cent. of true red lead has been on the market for some years. Then an unexpected fact was developed. The old red lead when mixed with oil would set in a day or so—often in a few hours—into a cement; just like plaster of Paris and water; this tendency made it work with difficulty and unevenly in application and its coarseness gave it a tendency to run; but the new, or high-grade, article is inactive to oil, and brushes out smoothly like a house-paint. This enables the painter to cover 50 per cent. more surface with the

same quantity and still get a coating having a uniform thickness which gives more protection than the thin portions of the paint formerly used. This secures greater economy, even at a slightly greater cost per gallon; and this is an economy not only in the cost of the paint, but in the labor, because the paint works more easily, and a man can cover more surface in a day; it also requires less skill, and, therefore, a less highly paid man, to do good work. For the last year or two, red lead ground in pure linseed oil has been offered to the trade as a paste ready to be thinned with more oil; such a paste keeps for a year or more, or indefinitely as far as known, like white lead paste. Its use saves time and waste in mixing, and, being ground through a mill, the mixture is perfect, which is not the case with hand-mixing; and, as it avoids the presence of a dusty pigment, it is more sanitary.

The only serious objection to the use of such red lead is that it dries more slowly than the older kinds. This can be obviated, however, by the use of a little japan drier. There is a well-founded prejudice against the use of excessive quantities of drier in any paint; but it should be remembered that red lead paint mixed in the (standard) proportion of 28 lbs. of pigment to gal. of oil, contains 20¼ lbs. of pigment per gallon of mixed paint. If this pigment contains 15 per cent. of litharge, it has 3 lbs. of litharge per gallon. Now, ordinary, good lead japan driers, or lead and manganese driers of approved quality, contain the equivalent of 1 lb. of litharge in about 3 gals. of drier; and 3 lbs. of litharge will make 8 or 10 gals. of drier. To make 1 gal. of mixed 94 per cent. red lead paint dry requires only 1 pint of drier; the rest is excess. It is much safer to add the desired quantity of drier. It may be asked why the litharge in the 94 per cent. red lead is not more active; it is probably because, when the peroxidation of the lead has been carried so nearly to completion, the particles of litharge are enveloped so completely by a dense coating of true red lead that the oil does not reach them. This is obviously not the case with the commoner and less thoroughly oxidized pigment.

It has sometimes been suggested, by those not very familiar with the chemical questions involved, that the litharge is the essentially valuable part of the paint, and that the red lead is only an inert extender. This is not so. The whole history of the subject shows that the improvement in red lead for paint during the last twenty-five years has been made by reducing the litharge contained in it; litharge alone, or used with other pigments, has not been satisfactory, though orange mineral, which is red lead free from litharge, is most excellent, and would be used if its cost were not so great. Further progress will undoubtedly produce red lead with a lower percentage of the protoxide; in fact, the 94 per cent. red lead now in the market usually contains much more than 94 per cent. of true red lead.

Progress has also been made in our knowledge of linseed oil. Within a few months, the American Society for Testing Materials has adopted specifications for North American raw linseed oil, which is of better quality than that made from South American seed. These specifications are the result of a great deal of work by many of the best oil chemists, and it is now possible for any good analyst to tell whether or not an oil is pure and good. Methods of paint analysis are in general being standardized; and a vast amount of work is going on in Germany and England, as well as in the United States, on the chemistry and nature of drying oils. At present, linseed oil has adulterants, but no substitute; China wood oil is a valuable drying oil, more valuable for some purposes than any other, but, as an oil for ordinary paints, it is used, as far as the writer knows, only to cover up the use of non-drying oils, which must be regarded as adulterants. At present prices, it is not likely to be used even in this way. Fish oil is used to some extent, as it always has been, in paint for roofs and smokestacks; but one should not be disturbed by talk about the "newer paint oils," for, except China wood oil, there are none.

In closing, Mr. Sabin mentions that the committee appointed by the American Society for Testing Materials has made a final report on the condition of the paints on the Havre de Grace Bridge; as is well known, this bridge was painted six years ago by a committee of that Society, which committee included several members of the American Society of Civil Engineers. This report describes three of the paints as excellent; two of these were straight red lead in oil, and the third was red lead, with about 15 per cent. of a pulverized silicate added, in oil, the red lead being about 98 per cent. true red lead. Nine other paints, of varying composition are reported as affording generally effective protection to the structure. As all these paints were carefully applied, it is fair to conclude that the durability of any good paint may be increased one-half, and probably doubled, by proper care in its use as compared with average practice. It is only by continually reiterating this fact that we shall ever secure the most elementary and fundamental requirement for the economical treatment of structural steel.

PRESERVATION OF WOODEN WATER PIPE.

Since the durability of wooden pipe depends entirely upon its continuous and perfect saturation with water, it follows that the pipe should be thin enough to insure penetration of the water through its pores at a more rapid rate than the loss of water by evaporation from its surface.

The porosity of timber differs to such an extent that a proper thickness of shell of a red cedar pipe, for example, is too great a thickness for Washington fir. Obviously a thickness that is proper for a pressure of 40 pounds per square inch is too great for a pressure of 10 pounds per square inch.

This curious condition of fairly well-recognized facts is pointed out by Engineering and Contracting, which says further that these are fairly well recognized facts, but not until comparatively recently have engineers begun to consider the external conditions that affect the life of the wooden pipe. Enough instances of long life of wooden pipe buried in clay are on record to establish the fact that clay is an admirable preservative.

The reasons for this are probably twofold:—Clay holds moisture and thus insure continuous and thorough saturation of the wood at the surface of the pipe; and moist clay is not a good culture bed for the growth of fungus that causes rot.

In view of the preservative quality of clay, it is asked would it not be good engineering to encase wooden pipe with clay several inches thick? Where the clay is within comparatively easy reach, and particularly where the trench is in soil that is either very porous or contains much vegetable humus, it would seem that a clay jacket around wooden pipe would prove economic. A concrete jacket might serve a similar purpose, but ordinarily at a greater cost than clay.

The lock-gates and sills of the Panama Canal are all made from "Greenheart," a large tree found in the dense jungles of northern South America, especially British Guiana. The wood will bear, without crushing a weight of six tons to the square inch, and will remain sound 100 years under water, being immune to the attacks of the salt water teredo.

TRANSMISSION LINE WORK.

By Ernest V. Pannell, A.M.E.E.,
Chief Engineer, The British Aluminium Company, Limited, Toronto.

DEVELOPMENTS in transmission line practice during recent years have insistently sounded the keynote of reliability. With increase in operating pressures from 40 and 60 up to 130 and 150 kilovolts it has been realized that the weakest part of any power system is the transmission line and practice has shown the weakest link in the transmission line to be the insulators. Notwithstanding the relative perfection to which insulator design and construction have been brought it has still to be accepted as an axiom that the fewer the insulators the less will be the risk of breakdown. This has been the chief factor urging the adoption of long spans in transmission line work and the long span has called forth the very best properties of conductor material in general; moreover, it has brought into the field the reinforced conductor by which is understood a wire or cable in which the tension is carried mainly by a core of high tenacity steel wire.

When aluminium was first used for transmission purposes the opponents of this material asserted that a metal of such relatively poor physical properties would be useful on the very shortest pole-spacings only. Improved manufacturing methods and better understanding of the laws of sag and tension have assisted to make the long-span aluminium line an every-day engineering proposition. It is granted that the sag will be greater with aluminium than copper and that the towers will, as a rule, be more costly. Aluminium is, however, in most countries and under usual market conditions, so much cheaper than copper that the credit balance more than pays for the extra high structures. The relative economy effected by the use of aluminium is, however, powerfully influenced by the conditions under which the line is put up. Under what may be called northern conditions, figuring with ½" ice and a wind velocity of 65 miles per hour, the sags will be much greater and towers more costly than where the line is being laid out in California or Mexico where no ice or snow have to be allowed for. It is proposed in this article to discuss only northern conditions, so that any conclusions which tend to be unfavorable to the light metal may be reversed with a change in latitude. The maximum vertical summer sags on equivalent sizes of copper and aluminium conductors are shown by the curves in Fig. 1. The constants on which these curves were calculated are as follows:—

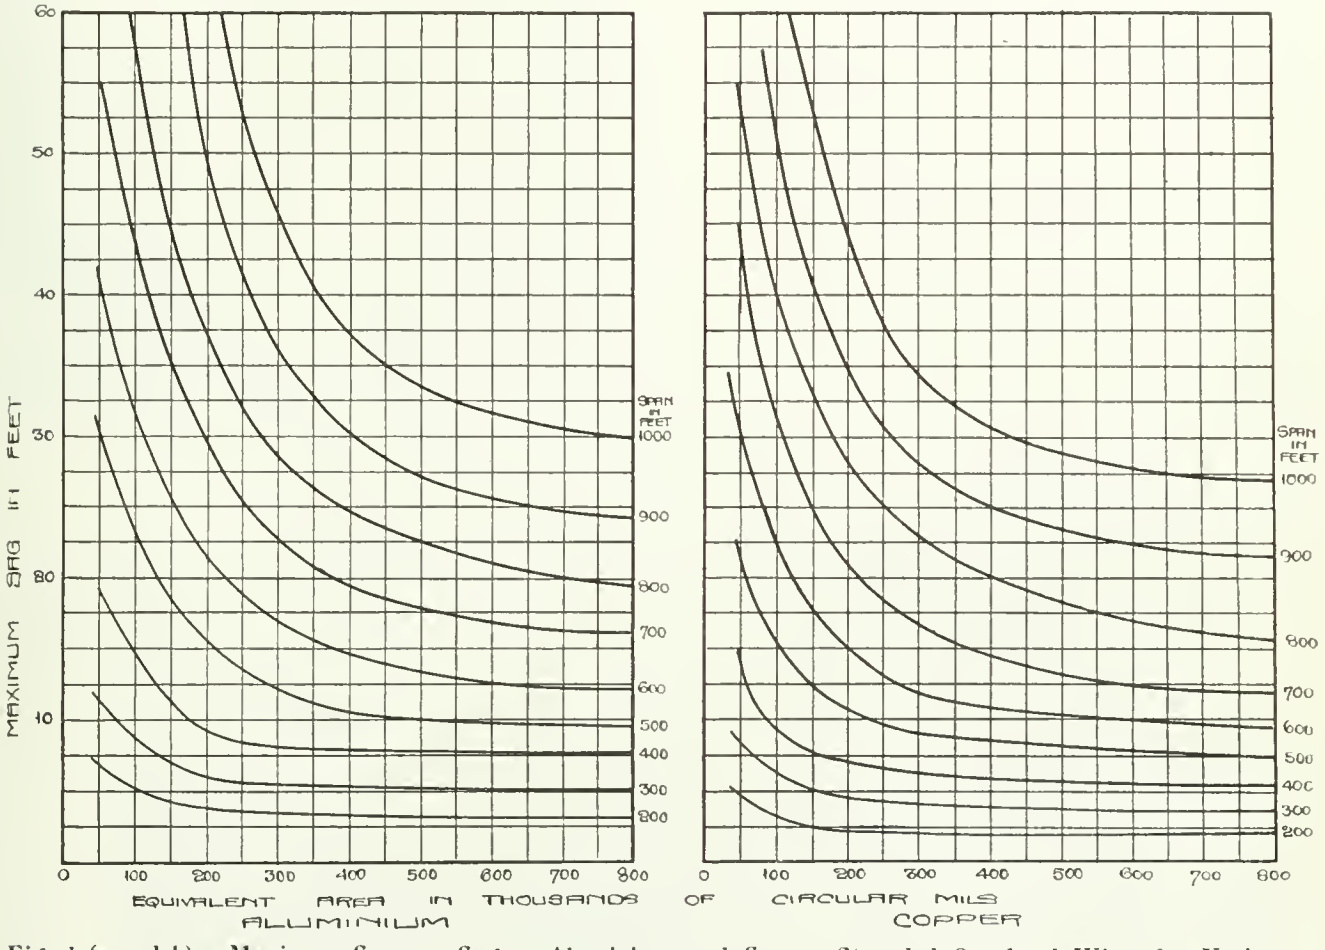

Fig. 1 (a and b).—Maximum Summer Sag on Aluminium and Copper Stranded Overhead Wires for Various Lengths of Span.

	Aluminium.	Copper.
Tensile strength, lbs. per sq. in.	28,000	60,000
Yield-point, per cent.	75	60
Working stress	14,000	30,000
Per cent. extension per deg. F.	.00130	.00093
Modulus of elasticity	9,000,000	12,000,000

The design of transmission line towers is at the present stage of development a somewhat complex subject, as there is no recognized standard for the type to be em-

ployed, tests to be fulfilled, weight of sections, etc. The weights and cost of towers of different types for precisely the same class of service vary enormously. It is possible, however, given a properly worked out design, to deter-

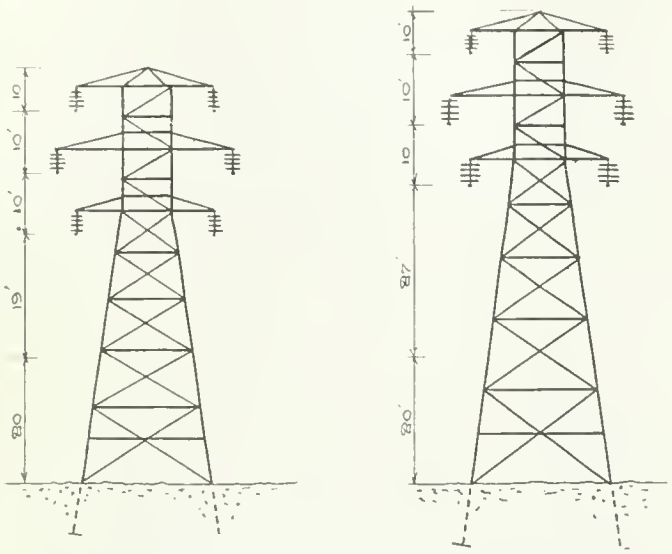

Fig. 2.—Towers for 2/0 Equivalent Copper and Aluminium Conductors on 600-Foot Spans.

mine how the cost and weight of the structure will be influenced by changes in the sag or span. Taking a practical instance: suppose it is desired to run a double-circuit three-phase 100,000-volt line across level country with 600-foot spans and copper conductors, size 2/0, B. & S. The type of tower assumed is shown in Fig. 2(*a*) and its height is determined by allowing the usual clearances and adding the amount of the maximum sag, found from Fig. 1 to be 19 feet. As is seen, the total height of the tower from the ground up will be 69 feet and its weight, including the extension angle footings, will be 5,000 lbs. This would function as a dead-end or corner tower, as it would be capable of carrying tests of greater severity than those usually specified for suspension towers. Now, any change in the height of the tower will increase the moments and stresses coming upon the main members, so that the weight will be increased once due to the greater height and once again because all the sections will have to be thicker to give them the necessary stiffness. In short, the tower weight will vary as the square of the height. Expressed in symbols, $W = mH^2$ where W is the weight in lbs., H, the height in feet and m is a constant depending upon the number and size of the wires and whether a suspension or dead-end tower, for the present instance m has the value of 1.05. Considering now the aluminium equivalent of the above copper cable, its maximum sag is found from Fig. 1 to be 27 feet; the tower, to give the same clearances as before, will, therefore, be 77 feet high. The extra size of the conductors will not be sufficient to call for any increase in the value of m so the weight of the tower in this case is $W = 1.05\ (77)^2 = 6{,}200$ lbs. Allowing a base price of 4 cents per lb. for the tower sections drilled, galvanized, bundled and delivered on site, the extra cost on the towers for the aluminium line will be $420 per mile. This need not be so high as the structures are unnecessarily heavy, and lighter towers might quite well be interspersed along the run of the line. Allowing this item to stand, however, and taking present-day average bases of 18 cents for copper wire and 25 cents for aluminium, however, the use of the latter will save $730 per mile, so that on this particular size of conductor there is a broad margin in favor of aluminum after allowing for the more costly tower line.

Fig. 3.

A point which has to be considered where a tower or pole line has to support conductors of very large area is that the tension along the line is likely to be very much more than the wind pressure acting laterally on the wires. In other words, the severest strain which may be put upon the tower is not that of a gale of wind blowing sideways on to the line, but the effect of two or more conductors breaking in the same span. Under these conditions the towers for an aluminium line frequently figure out lighter and cheaper than those for use with copper, owing to the fact that the maximum tension in the former case is about 25% lower than in the latter.

Fig. 4.

The most difficult problems in connection with long-span work are those associated with river crossings. Here not only has a long distance between supports to be negotiated, but the clearance has usually to be extra high so as not to impede navigation and frequently restrictions are laid upon the maximum stress in the wires which greatly increase the complexity of the problem. In most cases matters are considerably simplified by the adoption of a larger size of conductor than that used on the run of the line. For instance, take a 1,000-foot span across a river which is to be crossed by 6 aluminium cables, the size employed along the line being 200,000 cir. mils. The maximum sag on this size will be 65 feet and, allowing 50-foot clearance above the navigation channel with banks 10 feet high, the height of the towers will not be much less than 120 feet. If, however, the cables be increased to 300,000 c.m., the sag will be reduced to 45 feet and the towers consequently to 100 feet. Needless to say, this diminution would be well worth while. Considerably larger sizes of aluminium cable are in use on long spans, the Southern Pacific Railroad having four 2,000,000 c.m. stranded aluminium cables spanning 1,300 feet across a branch of Oakland Harbor. In this case, as in the original spans across the Niagara Gorge, the cables are dead-ended at one end and run over pulleys and weighted at the other so that the tension is constant whatever the weather conditions. On the Southern Power Company's lines in North Carolina 2/0 aluminium conductors are run with 1,500-foot spans with sags very little greater than on the parallel copper wires. Of course, in this latitude no ice or snow are encountered and sags may be correspondingly short.

The illustration (Fig. 3) shows a view on a very remarkable transmission line in Norway. Twenty 3-phase circuits of 600,000 circular mil aluminium cables convey 170,000 kva. along a steep mountain-side. The spans average 700 feet in length and the district is a stormy one, considerable sleet and severe winds having to be reckoned with. Before installing the line the then chief engineer, Dr. F. W. Marguerre, made a number of experiments in order to try out thoroughly the rival merits of copper and aluminium line wires. All things considered, it was found that the light metal offered the most important advantages in this instance. Aluminium wire having the relatively low tenacity of 24,000 lbs. is used and is strung to give its maximum tension at minimum temperature with a ¾-inch ice-coating and a wind-pressure of 14 lbs. per square foot on the projected surface of the cable. A flexible tower line is employed with heavy strain towers at intervals. Among other experiments, tests were made to determine the minimum spacing which would be safe to adopt between conductors on a 700-foot span with the results that 48 inches was adopted.

In Fig. 4 is shown a standard tower on another recently constructed transmission line in Norway. These towers are designed to carry four 3-phase circuits of 260,000 c.m. aluminium conductors. In this case, again, the average tower-spacing is about 700 feet. This appears to be becoming a European standard for tower lines. At several places where rivers and marshy ground have to be crossed spans up to 2,000 feet are encountered. At these places special towers are used and extra high tenacity aluminium wire is strung. Very great care is

Fig. 5.

taken in the manufacture of this cable with the result that its tensile strength is about 38,000 lbs. per sq. in. It is, however, only stressed up to 13,000 lbs., so as to allow an ample safety factor. So far, this would appear to be the longest span upon which aluminium has yet been tried, and although the line has been in operation for nearly two years the engineers report having had no trouble. There seems, indeed, no reason to doubt that, with careful design and stringing, aluminium will prove a thoroughly satisfactory material for even the longest spans. The two principal troubles likely to be experienced are due to improper methods of tying on to the

insulator or to insufficient spacing. In the present instance the insulators (which are duplicated on the long-span towers) are fitted with lead-lined clamps. Any abrasion is, therefore, taken by the soft metal. The spacing between conductors was, after careful tests, fixed at 69 inches.

In this country less attention has been paid to the possibility of improving the physical properties of aluminium *per se* than has been done in Europe; engineers have in general been more attracted by the possibility of reinforcing the aluminium cable by means of a steel core. The view in Fig. 5 shows a 1,000-foot ravine span which is crossed by three steel-reinforced aluminium conductors. (This transmission line was described in the "Electrical News," Vol. XXII., p. 34). The arrangement of a typical steel-core cable size 3/0 is shown in Fig. 6. It has to be remembered in dealing with this class of cable that when the maximum wind and ice stresses come upon

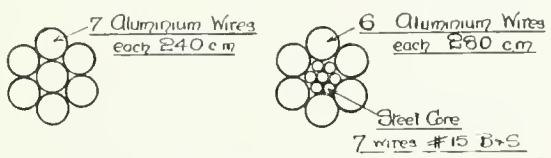

Fig. 6.—3/0 Aluminium Cable and 3/0 Steel-Core Aluminium Cable.

it all the tension will of necessity come upon the steel due to the fact that the aluminium will elongate about three times as much. The core must, therefore, be at least as strong as the rest of the conductor. As, however, the section of the steel is only one-sixth of the aluminium, it must have a tenacity not less than six times as great. A typical specification will be as follows:—

	Aluminium.	Aluminium-Steel.
Size B & S.	3/0	3/0 equiv.
Circular mils (aluminium) ...	167,805	167,805 equiv.
No. Aluminium wires	7	6
Diameter each, inches	.155	.166
No. of steel wires	—	7
Diameter each, inches	—	.057
Diameter of cable, inches..	.465	.498
Diam. of cable with ½" ice.	1.465	1.498
Weight per foot, lbs.	.155	.216
Weight per ft. with ½" ice.	.755	.819
Total loading per foot.....	1.234	1.290

From the above it will be seen that the extra weight and diameter of the steel does not increase the loading to any great extent. The tensile strength of the aluminium may be taken as 28,000 lbs. per sq. in. and that of the steel as 220,000 lbs., the working unit stresses will be safely assumed at one-half these figures respectively. Now, as the area of the steel is one-sixth that of the aluminium, the tensions in the two classes of cable will have the following ratio:

$$\frac{\text{Steel}}{\text{Aluminium}} = \frac{220{,}000}{28{,}000} \times \frac{1}{6} = 1.31$$

It is, therefore, possible for the same safety factor to put approximately 31% greater tension on the aluminium-steel cable. This will, in most cases, reduce the sag by 25%, and under certain circumstances would be well worth the extra expense. In most situations, however, the writer is inclined to favor the European principle of manufacturing aluminium cable of the very highest grade and tenacity, so that reinforcing would be unnecessary.

PROPER INSPECTION OF TRACK PAVING.

THE following instructions to inspectors have been developed by Messrs. D. H. Roszel and H. H. George, and adopted by the Public Service Railway Company, of Newark, N.J., upon the recommendation of Mr. Martin Schreiber, Maintenance-of-Way Engineer. The object of these instructions is to secure full compliance with the contract and specifications and the performance of first-class work by the contractors in such minor details as are not generally specifically mentioned, but are implied by the contract and specifications. Those relating to paving inspection are published herewith as outlined in a recent issue of the journal of the American Electric Railway Association.

General Instructions.—The inspector is to make out daily reports on forms provided for the purpose, and also to keep in a field book a detailed record of each day's work, which must contain the following:—

(a) The date of his assignment to the contract and the date of its actual commencement and completion.

(b) Detailed force account for each working day and the amount of material used.

(c) Condition of weather each day.

(d) Delays, reasons for, and the period of duration.

(e) Conditions of sidewalks along the line of paving, previous to commencement of work, to forestall any future claim for damages.

(f) Accidents: date of accident, names of persons concerned and witnesses, cause of accident.

(g) Any neglect or refusal on the part of the contractor to comply with the contract specifications.

(h) Damages to persons or property by reason of any act or omission on the part of the contractor.

(i) Oral instructions or orders received from his superior officer, and all other matters appertaining to the contract that might be worthy of record.

(j) A record of the various types of paving used (such as new, clipped or unclipped block and their kind, sand, cement or tar and gravel joints, etc.) and the exact terminating points of each type.

The inspector must be present on the work at all times when any work is in progress, unless excused by his superior officer.

It is the duty of the inspector to familiarize himself with the local conditions affecting the contract to which he is assigned, in order that the work at all stages may be so carried on as to cause the least possible inconvenience to the operation of the cars, and to the public generally. The street must not be unnecessarily obstructed, and the contractor must provide temporary passageways at crossings, and wherever else necessary.

The inspector must not permit the contractor to interrupt the trolley traffic during the course of the work, and must see that no materials are permitted on or near the track, that will interfere with the operation of cars or the safety of passengers.

All materials, as they are brought on the street, must be piled compactly and neatly at such points as the inspector shall designate, and in such a way as shall comply with the regulations of the municipal authorities. All loose material, excavated matter, and rejected materials must be removed from the site as soon as possible.

Special care must be taken that no material is piled around city fire hydrants, and that the space in front of same is kept clear at all times, and accessible to the fire apparatus.

The inspector shall see that all necessary signals and warning signs are placed on the work to protect the public, and that red lights are properly placed at the close of each day's work.

The inspector must see that the city monuments and bench marks are preserved from injury by the contractor. In case it becomes necessary to move or lower any monument, the inspector shall notify the Division Engineer, and the contractor shall not move same unless so instructed by the Division Engineer.

The inspector is to examine the material as it is brought on the work and see that it conforms to the specifications before permitting it to be used. Should the inspector at any time suspect that the material used is not in accordance with the specifications, samples must be taken by him, with a record of the location, and the office of the Engineer of M. of W. or the Division Engineer notified immediately.

The inspector shall not permit any portion of the paving to be laid at a higher elevation than the top of the head of the rail.

The inspector shall see that the void between the head and the base of the rail is filled either with the paving, or a suitable rail plaster, and shall not permit the contractor to pave against the rail unless this void has been filled.

Where block paving is to have tar and gravel, or cement joints, the inspector shall see that such tar or cement is omitted for a sufficient space around each joint, until the joints are electrically welded, provided such joints are to be so welded.

The inspector shall report to the Division Engineer any variation from the ordinary paving that will require special measurements, and shall keep sufficient records to be able to designate such places until same shall be measured by the engineers.

The inspector shall notify his superior officer at once of any accident, no matter how slight. If the accident is serious the inspector shall immediately notify the claim department by telephone.

In addition to the above general instructions, the inspector shall watch out particularly for the following points: (This is not to be construed by the inspector to mean that they are the only items to be checked; but he is to keep a close supervision over the entire job.)

Concrete.—Cement must be effectually protected from water or dampness. Packages of cement, which when turned out contain hard lumps, should be rejected.

Where the contractor is to place the concrete foundation for the paving, the inspector shall see that the specified proportions are strictly adhered to. Where the sand and stone is supplied to the mixing board by wheelbarrows and the cement in bags, the inspector shall measure same, to see that the contractor is using the right proportions of cement, sand and stone. One standard bag of cement will be considered as one (1) cubic foot, and a barrel of cement as four (4) cubic feet.

In mixing the concrete, the inspector must see that the directions of the specifications are followed. The method of ganging the proportions must be accurate, and the operation of mixing it by hand must be done on suitable mixing boards. The ingredients must be thoroughly mixed. The inspector must see that the concrete is deposited as quickly as it is mixed.

When a concrete mixer is used the inspector must acquaint himself with the theory and principle of operation of that particular type of mixer, and be able to detect at any time any change in the proportion or uniformity of the mixture.

When the mixer is of the automatic-feed type, the inspector must test it at least once during each day's work, at times unexpected by the foreman, by feeding measured quantities of cement, sand and stone, in the proportion specified, into the respective hoppers. If the mixer is gauged properly and feeding freely, the measured quantities of materials will be exhausted simultaneously. Should some cement be retained in the cement hopper after the sand and stone are exhausted, it is sufficient indication that the mixer is either improperly gauged or that the cement feed is clogged. Whatever the trouble is, it must be corrected before the mixing is allowed to continue.

When the contractor employs a concrete mixer into which the materials are not loaded in batches, the inspector is not to depend for the securing of proper proportions on the accuracy of the machine gauging or the proportion of the shovelers used. The material must be placed in properly proportioned piles, not containing more than 10 cubic yards in the case of sand, broken stone or gravel, and the inspector must see that the machine exhausts all material simultaneously. Should it be impossible to obtain these results, due to improper piling of material, the inspector must require the use of measuring boxes for proportioning the charges for the mixer.

Use sufficient water to make what is called a wet mixture, but not so much that free water will drain from the mixed batch before ramming.

The test for the degree of mixing or turning will be that all fragments of stone are fully covered with mortar.

Grouting of concrete after it has been laid, or the application of neat mortar to the surface, and the sweeping of the surface with street brooms to make it smooth or to cover up defects, must not be permitted. Concrete made of fine stone in the stated proportions of mixture may be used for the leveling up of depressions.

The inspector shall see that the concrete is protected from injury while setting, and that no hauling or trucking over it is done, except on planks, and only after a proper hardness has been reached.

Sheet-Asphalt Pavement.—The principal care of the inspector will be to see that the asphalt is not laid at too low a temperature. The minimum temperature permitted by the specifications is 250° F. While the main or interior mass of a wagon-load may be well above that temperature, the top and outer part of the load may be, particularly in cold weather, too cold to be safely used. Some of this colder portion may be sufficiently reheated by mixing it with the hotter material, if properly handling in unloading; but any material that is so cold as to be lumpy when unloaded, or, more particularly, when being raked out, should be discarded. This applies to both surface and binder mixtures. The best practical guide is the manner in which the mixtures behaves in raking. It should always be so hot that it will, under the rake, break up into a uniform crumbling or powdery mass. If it does not do this it is too cold, whatever its temperature may be.

Preparation of Street Surfaces.—Before the binder is laid, all loose material, rubbish, street dirt and other matter foreign to the concrete surface, shall be removed and the concrete surface swept, with street brooms if necessary, to properly clean it.

Neither binder nor surface mixture shall be laid upon wet surfaces. Before the spreading of the surface mixture on the binder, the latter must be cleaned of all foreign matter and swept if necessary. If the binder course already laid has become covered with mud from wagons or other travel, it must be swept clean. No loose fragments of binder material must remain on the surface. Any part of the binder course

that may have become broken or loosened must be taken up and new material laid in its place with the same care as the original.

Laying Binder Course.—Nearly the same care in raking and equally as careful rolling should be required as for the surface course. If the binder is not thoroughly compressed and becomes cold before the surface course is laid, it is likely, in the future hot weather, to soften and yield under heavy travel, and thus start small depressions in the pavement.

Laying the Surface Course.—The joints against a cold edge of previously laid surface must be cut back until solid, fully compressed material of full thickness is reached, and the raw edge completely but thinly painted with liquid bitumen. No masses or fragments of cold mixture must be allowed to remain on the surface of the binder, in advance of the placing of the surface course, to be covered up by the latter. Such cold masses will not be compressed by the roller, but will later, under the hot sun and heavy travel, yield and start depressions in the pavement. The raking requires to be properly and skilfully done. The tines of the rake must penetrate to the binder, so that the raked material will be a uniform mass from top to bottom.

Rolling.—The inspector must insist upon the roller being placed upon the freshly raked surface just as soon as the material will bear it without being squeezed out or displaced laterally. The tendency is to keep the roller off too long, thus permitting the chilling of the surface and preventing its proper compression. The inspector must not take the contractor's word as to how soon the rolling may be begnn, but should have trials made until he is able to judge for himself.

The rolling of the heavy roller should be very thorough; the roller should be kept at work constantly until the surface is too cold to be impressed. In operating the roller lengtnwise of the street the rolling should begin at the gutters and work toward the centre of the street whenever practicable. Cross rolling and diagonal rolling must be insisted upon wherever the width of the street will permit.

Asphalt surface must not be laid when rain or snow is falling or so long as the surfaces are wet. Surface mixture raked out and caught in a shower before it is well enough rolled to exclude water must be taken up and discarded.

Block Paving.—The more important things for the inspector to look after are:—

(a) The quality and shape of the blocks.
(b) The sand cushion.
(c) The setting of the blocks.
(d) The ramming of the surface.
(e) The filling of the joints.

The Blocks.—Assuming that the general quality of the stone has been approved, the inspector will need only to observe and reject blocks made from soft, weathered or otherwise defective stone. Any material divergence from the correct form, or from the sizes specified as permissible, will be readily caught by the eye as the blocks are brought to the street, and such defective blocks thrown out.

The proper dressing of the blocks is important, and should be watched carefnlly. While the inspector is not expected to examine each individual block, close observation of the blocks as they are handled and laid will enable him to detect and reject those that are materially defective in shape or dressing; or excessively wide joints will call attention to them as they are set.

Sand Cushion.—Screened sand must be used for the cushion bed. It should be moderately coarse and must be fairly clean and pure. The tendency with contractors is to use any dirty sand or sandy loam available on the street. Such material, especially if it becomes filled with water, will yield under the blocks and will not support them properly. The sand bed should not vary materially in thickness. It should be laid and graded not more than 50 nor less than 20 feet in advance of the setting of the blocks.

Setting the Blocks.—Blocks of uniform width and depth must be selected for each course, and each block must be laid upon a full bed of sand and "struck in" at the base, so as to bring the stone in close contact with its neighbor in the preceding course, and thus insure the closest possible joint.

The inspector must see that the joints in the line of traffic are close, and that the alignment of the course is true. This is most important, as a crooked or wavy course lessens the chances of getting close joints, not only along that particular course, but along the courses that are to follow. The inspector must see that all longitudinal joints are broken by a lap of at least 3 inches.

The operation of ramming is not to be permitted to approach within 20 feet of the end of the paving. After ramming, the surface of the pavement may look somewhat wavy and uneven. The inspector must then see that it is back-rammed. All blocks below the general plane of the surface must be raised and more sand placed thereunder, and the blocks rammed again to an even bearing.

Whether sand or grit is used for partly filling the joints before paving cement or pitch is poured, care must be exercised in placing the sand or grit in the joints. Dumping a wheelbarrow load on the surface and then sweeping the joints full is not to be permitted under any circumstances.

Sand and grit or gravel should be dried before being used and put into the joints as nearly as possible to a uniform height, as called for in the particular class of granite pavement.

For pitch joints, the contractor shall remove the gravel for the depth of about 1 inch below the surface before applying the pitch. The latter should be poured into the joint while at such a temperature as to be perfectly fluid.

Clipping Old Block.—In clipping, care should be taken that all blocks are of as nearly uniform size as possible, and that the sides are even and square, in order to insure uniform width of joints.

Any block that falls below the minimum specified size after clipping shall be rejected.

Wood, Asphalt Block, Brick Paving.—The inspector must use special care in the inspection of brick, asphalt or other artificial block, and reject and prevent the use in the pavement of any broken, chipped or otherwise defective blocks. A contractor will often use such brick and lay them with the defective side or face next to the sand cushion. This should not be permitted. The contractor should not be allowed to fill the joints of any stretch or section of paving with cement, pitch or other filler, until such paving has been thoroughly examined by the inspector for defective blocks, and such blocks replaced by perfect ones.

However carefully lumber may have been inspected before its manufacture into blocks, the subsequent seasoning, treating and handling will develop many defects, and yon will need to observe the delivered blocks closely and reject those that do not comply with the specifications.

Under certain conditions, wood blocks will develop a great many "season cracks" which should not condemn them unless the cracks open for the full depth and to more than one-third of the thickness of the block. What are called "shakes" result from the separation of the wood along the growth rings, and if well defined or open should condemn the block, though in many cases the blocks, after the defective part has been trimmed off, may be used.

The inspector shall see that the required crown is given to the concrete before the same is set, as on account of the even size of blocks, any inequality of foundation more easily affects the surface.

When these blocks are to be placed under the head of the rail (as in Tee Rail), the inspector shall see that they are placed tight against the web of the rail, and that all voids are completely filled, to avoid any loosening by the action of the cars on the adjoining rail.

Macadam Paving.—The inspector must see that the stone is spread in a uniform layer to the specified depth before rolling, and that the rolling is continued until the stones are thoroughly settled into place, and show no movement under the roller.

The inspector shall see that the binder is applied in thin layers, and that it is not rolled until dry. The application of binder with intermittent rolling must be continued until all the voids in the stone shall have been filled. He shall then require water to be applied in such quantities that a wave of mud forms in front of the roller. The rolling must continue until the pavement is thoroughly consolidated.

The inspector shall see that the road is again rolled after the final coat of screenings is spread over the surface. He shall not accept the same until the surface becomes thoroughly consolidated, hard and smooth.

Before the application of a bituminous dressing, the inspector shall see that the surface is so swept that the ends of the one and one-half inch stones are exposed. Such dressing must not be applied except when the temperature is above 50° F., and the weather is clear.

The inspector will bear in mind that the foregoing instructions are general and intended as a guide to be used in conjunction with, and as a supplement to, the contract form and specifications. He must not conclude that, because no mention is made of some specification provision in these instructions, they are of minor importance and may be neglected or violated. He must remember that the contract specifications govern in every case, and will be held to strict accountability for the enforcement of every and all provisions contained therein.

TORONTO ASPHALT SPECIFICATIONS.

SPECIFICATIONS for the supply of asphalt for the city of Toronto for the year 1914 were issued last week by City Engineer George C. Powell. The following portions will be of interest to municipal and highway engineers and road contractors:—

All asphalt herein shall be obtained by heating crude natural asphalt or crude asphaltic petroleum without the admixture of any other material to a temperature of 400 degrees F. until all the water and light oils have been driven off, and the refined asphalt thus obtained must meet the following requirements, viz.:—

(1)—It shall contain not less than 90 per cent. of "Bitumen."

(2)—Not less than 98.5 per cent. of its "Bitumen" shall be soluble in carbon tetrachloride at air temperature.

(3)—Not less than 65 per cent. of its "Bitumen" shall be soluble in standard petroleum naphtha at air temperature, and the word "Bitumen," as used in these specifications, shall signify and shall be taken to mean "any hydrocarbon, or hydrocarbons, soluble in carbon bisulphide at air temperature.

(4)—It shall not contain more than 15 per cent. of fixed carbon on ignition.

(5)—Fifty grams of refined asphalt, when heated in an open flat-bottom cylindrical dish, 2⅞ inches in diameter and 1¼ inches high, shall not lose more than 5 per cent. of matter by volatilization at 325 degrees F. in twenty-four hours.

(6)—It shall not be softer than sixty penetration at 77 degrees F. (Dow Machine).

(7)—It shall not be harder than that which will require more than 15 per cent. of flux, calculated on the percentage of "Bitumen," to produce an asphaltic cement of forty-five penetration at 77 degrees F.

(8) The flux used in the preparation of the asphaltic cement above mentioned, will be any suitable standard flux having a specific gravity at 6 degrees F. between 0.9395 and 0.9722.

(9)—All asphalt herein shall be subject to the approval of the Commissioner of Works and be tested at destination.

An affidavit must be submitted with each tender, showing where the material was mixed or the source of supply, and also stating where it is refined and the method of refining, and further stating that nothing whatever has been added to the crude natural material.

The asphalt must be shipped in strong, light packages, capable of being handled in all temperatures, and the gross weight must be marked on each barrel or container. In addition, a list must be forwarded prior to each shipment showing these weights, and upon arrival the weight of each barrel or container, will be checked on the city scales. Should any discrepancies in the weights appear, then the weights as shown on the railway manifest shall govern, for establishing gross weights.

Tenderers must submit a sample lot of not less than two pounds of refined asphalt, together with an analysis of the same, made and certified by a properly qualified chemist, of each class tendered upon at least forty-eight hours before date set for reception of tenders, samples to be addressed to the Commissioner of Works, City Hall, Toronto, plainly marked as to grade and class and by whom submitted. These samples will be subject to the approval of the Commissioner of Works, and will be taken as a guide in considering any asphalt required or delivered under this contract.

The percentage of "Bitumen" found by analysis of the samples submitted with the tender, shall be taken to be the "minimum percentage" of "Bitumen" which the proposed grade of asphalt shall contain, and the award shall be made on the price per ton of "Bitumen" calculated from the percentage of "Bitumen" thus found.

The following is a list of municipally-owned electric railways in Canada: Berlin and Waterloo Street Railway, Calgary Municipal Railway, Edmonton Radial Railway, Guelph Radial Railway, Lethbridge Municipal Railway, Regina Municipal Railway, St. Thomas Street Railway, Saskatoon Municipal Railway, Brandon Municipal Railway, Port Arthur and Fort William Electric Railway and Toronto Civic Car Lines.

PARAFFINE SCALE AND DUCTILITY.

By Leroy M. Law,
Chemist, United States Asphalt Refining Company.

THERE are other tests, besides the Fixed Carbon Test, appearing in some specifications for asphalt supply, which should be omitted until their status is better estabilshed. Among these are the tests for "paraffine scale" and "ductility."

The so-called paraffine determination is supposed to show the amount of hard or "scale" paraffine present in refined asphalt, and is, therefore, considered to be an index as to its liability to crack in cold weather or to granulate with age.

The general procedure employed in this determination is doubtless familiar, consisting of distilling the material rapidly down to dry coke and collecting the distillate. The latter is then weighed, an aliquot portion removed, dissolved in alcohol-ether, chilled, and the crystallized scale filtered off, dried and weighed. Many specifications prescribe that the scale shall not exceed a certain figure, yet few of them prescribe their modifications in detail.

The result is that each customer performs the test in a manner most agreeable or convenient to himself, and the manufacturer must stand for the whims and modifications that the customer may see fit to introduce. Usually the test is conducted in a glass retort, yet some operators substitute in its stead an iron one. That this may influence results matters little, so the manufacturing chemist must visit all these laboratories to become familiar with each chemist's details, then return home and endeavor to duplicate conditions.

Dow and Smith, using an iron vessel, have shown the effects of different rates of heating, type of condenser, etc., and they express the belief that at certain heats soft paraffines may be converted into the scale form. In the face of these experiments and opinions, we have chemists who insist that the higher the paraffine scale obtained the more accurate the method, their claim being that "you cannot get out more than there is in it."

In an effort to learn something as to the paraffine test as generally applied, the six laboratories who replied to the fixed carbon inquiry (see *Canadian Engineer* for Nov. 20th, 1913), were also asked to determine paraffine scale in the same samples. They did so with the exception of one laboratory, which, for reasons not stated, declined to make the determinations. I trust that laboratory E realizes the unscientific status of the paraffine scale test, and it was this realization that prompted them to decline to report on the subject.

Results on Paraffine Scale.

	Sample No. 213. Per cent.	Sample No. 215. Per cent.
Laboratory A.	3.6	2.8
" B.*	0.10	1.58
" C.	2.7	1.49
" D.	1.21	1.25
" F.	4.13	3.04

The above results tend to make a laughing stock of the profession, and are only printed with the hope that asphalt chemists may soon get together and study or eliminate these embarrassing subjects. Our company is furnishing a certain material to one customer, who limits paraffine to one per cent. From him we have had no complaint whatever, yet the same material is ineligible under another specification, having been reported to contain paraffine in excess of four per cent. Which chemist is right, and what is the manufacturer to do under such conflicting evidence?

Turning now to another requirement of questionable scientific value, and non-indicative of either quality or service results, I call attention to a requirement in many road oil and binder specifications which states that the material at, say, 50 penetration shall have a specified minimum ductility. The idea is that the bitumen shall possess adhesiveness, a quality best shown by the ductility test. By concentrating to 50 penetration, the standard consistency for this ductility test, all materials are brought to a uniform basis of comparison. Thus far the idea is sound, but the method of concentration—the all-important feature—is sadly neglected.

Some chemists, in a blind attempt at conserving ductility, stipulate that during concentration the temperature shall not exceed, say, 400° or 500° F. Others provide for "occasional" stirring, but generally they neglect the essential feature in asphalt treatment, namely, the agitation. In hardening the softer asphalts, agitation plays, if anything, a far more important role toward conserving ductility than does the mere restriction of temperatures.

My interviews with inspecting chemists relative to this test show that they are uniform only in following "no regular procedure." Some of them use heat-test residues which, by accident, have just reached 50 penetration, or again, this residue treated to a further heating on a hot plate or in an oven to obtain the desired consistency. Others concentrate the material from an oily state to asphaltic consistency in a single operation, either on a hot plate or in an oven, with or without agitation, as suits their fancy, and the manufacturer must ascertain, and duplicate in his laboratory, all of these eccentricities to find out the chance his material has of passing a so-called scientific specification.

On one occasion the writer submitted to a prospective customer a series of asphalt products varying in consistency from a maltha down to an asphalt cement. These were tested by the inspecting chemist, who passed the harder materials but rejected the softer ones as absolutely lacking in ductility when reduced to 50 penetration.

The chemist allowed me to look over his results, and I observed that with the material requiring the least concentrations he had secured the highest ductility, and in case of the fluid material requiring the greatest concentration to reduce it to 50 penetration, practically no ductility was obtained. All of the products were from the same primary material, the maltha, the harder ones being produced by refinery operations, which he or no one else could duplicate in the evaporation tins of an asphalt laboratory.

In the instance cited the chemist's process was undoubtedly one destructive to ductility, for the longer the heating required to reach 50 penetration, the lower the ductility of the product. The chemist avoided the issue by deciding that to his mind the test represented service conditions where no agitation of the material took place.

The two requirements above dealt with, together with the fixed carbon test previously dealt with, are examples of requirements without theoretical or practical significance.

*Material foamed considerably. Analyst is of opinion that there is no accurate method and results are only approximate.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MINING, MUNICIPAL, HYDRAULIC, HIGHWAY AND CONSULTING ENGINEERS, SURVEYORS, WATERWORKS SUPERINTENDENTS AND ENGINEERING CONTRACTORS.

"IN HONOR OF THE DEAN."

The twenty-fifth annual dinner of the University of Toronto Engineering Society constituted a re-union in honor of a man who, fifty years ago, came to the University of Toronto in search of an engineering training and who, finding none and foreseeing a profound necessity for such, proceeded to establish a foundation and build one; and whose labors, extending over thirty-five years of unceasing devotion to the cause, have produced an institution, still in the building, but now regarded as one of the important factors in the development of the Dominion.

It was a re-union in one of the drafting rooms of the old edifice through whose halls have passed generations of engineering students—familiarly known as the School, but which appellation has enlarged during recent years to include buildings of more modern and special design.

There are many things that might be said about Dr. Galbraith and his institution now known as the Faculty of Applied Science and Engineering of the University of Toronto. Pages might deservedly be devoted to his prominence in any one of many phases of the evolution of applied science and the development of engineering. As a criterion, as convincing as it is genuine, the expressions of student and graduate gratitude and of professional admiration that were in evidence upon the occasion mentioned, are sufficiently indicative of the indebtedness of a nation to the man for so diligently devoting his life and energy to the furtherance of technical and scientific education.

The remarkable assembly comprised prominent engineers from the chief centres of Canada, joined by leaders of the profession in United States, including graduates of years covering a full third of a century, and representative of the forces upon which the development of Canada has so materially depended—a strong phalanx of men of indomitable spirit assembled to do honor to John Galbraith, one of the builders of a Dominion.

A COMMISSION WITHOUT AN ENGINEER.

The following letter from the American Institute of Consulting Engineers, to the President of the United States, is largely self-explanatory. It is reproduced in these pages to exemplify the clear-cut purpose of the Institute to be of what assistance it may in the country's advance. It shows the altruistic motives behind the movement in the interests of a better equipped Interstate Commerce Commission, to rule the transportation forces of the United States, at the same time exposing the remarkable fact that the Commission, with so many duties that are pure engineering or closely allied to it, has worried along with no engineer on its membership, to be of service in the investigation of problems with which he might well be most familiar:—

Sir,—The American Institute of Consulting Engineers recently sought an appointment for its committee to present to you, orally, a request for the appointment of some able and experienced engineer to fill one of the vacancies on the Interstate Commerce Commission, with reasons therefor. A hearing having been found impracticable, the Institute has the honor to present its views through the medium of this communication. It is hoped that the argument that must be so briefly expressed here may so appeal to you that you will grant the hearing desired for the committee representing the Institute.

Membership in the Institute is limited to engineers in independent private practice of such experience and professional standing as enables them to serve their clients in an advisory or executive capacity; therefore, the membership consists only of the older or more experienced engineers Among its members are several of the past presidents of the national societies of Civil, Electrical and Mechanical Engineers.

The Institute has no candidates to present for office, and is, therefore, enabled to address you from an impartial standpoint, free from personal ambitions, and solely in behalf of the public interests.

The Interstate Commerce Commission is charged not only with the regulation of transportation rates, but also with the regulation and inspection of safety appliances used in our railways, with the investigation of accidents, and with the stupendous and expensive task of making a physical valuation of the railways of the country (United States); consequently many of the duties of the Commission are highly technical.

The leading part taken by the engineer in surveys, location, construction and operation of the railroads, gives him special training, skill and acquaintance with their details which would be of the greatest value in the study and decision of the cases that come before the Commission, and particularly in the executive work of physical valuation. Heretofore, with but few exceptions, the Interstate Commerce Commission has included no member having previous training or experience in the peculiar and complex problems that have come before it, and the knowledge and training had to be acquired after appointment.

We submit that while several years are required for a lawyer, politician or other layman to become familiar with the technical details of rail transportation, the engineer, on the other hand, is already acquainted with them. He can examine the details and special facts presented for adjudication without loss of time or unnecessary expense to the public through lack of preparation. With one or more engineers as members of the Interstate Commerce Commission we believe that the duties and responsibilities of the other Commissioners would be greatly lightened.

While the regulation of rates is not wholly an engineering question, the knowledge of the experienced railroad engineer would be helpful and valuable in its consideration. The economic and commercial factors underlying the rate structure are more familiar to him than to any other except the traffic expert.

Safety appliances and the investigation of accidents on the railways are matters wholly technical, and an engineer commissioner would, therefore, render inestimable service in reviewing the reports of inspectors and giving them proper value. The decisions and recommendations upon the subject of safety appliances, such as block signals and steel equipment, promulgated by the Interstate Commerce Commission, would be authoritative and command the respect and confidence of the general public and of the carriers if participated in by well-known engineers.

The physical valuation of railways is, perhaps, the most important engineering work now being done in this country. Its cost will be great, it has little useful precedent, and the whole responsibility for the task rests with the Commission. While the Commission will be aided, of course, by engineering boards and experts, the work will be dominated and directed by the Commission.

The results of this great work will be of vital import to all classes of society, and the well-being of the investor, shipper and laborer is bound up in the outcome. Moreover, the scrutiny that the valuation must undergo before the courts, the railroads and the general public makes it important that the decision of the many elements entering into the valuation should not be left by the Executive entirely in the hands of a Commission upon which the engineering profession is unrepresented. We respectfully suggest that an Interstate Commerce Commission, including in its membership one or more engineers, would arrive at an authoritative and equitable valuation, in which all concerned would have confidence.

While urging the appointment of an engineer on the Interstate Commerce Commission, we do not maintain that technical knowledge constitutes by itself a sufficient qualification: a judicial temperament, executive ability and tact are as necessary for a useful engineer member of the Commission as for any other; if therefore you decide to appoint an engineer, we ask that you select one having these essential qualifications as well as the highest professional attainments.

An engineer of the type we ask you to consider will not serve in a subordinate capacity under laymen, but would probably make personal sacrifice for the honor of serving under your administration as a member of the Commission and with the thought of performing a duty as a citizen.

We repeat that we have no candidate to offer and no motive except to serve your administration.

Respectfully submitted,

American Institute of Consulting Engineers.
Alfred Noble, President.
Eugene W. Stern, Secretary.

New York, Nov. 26th, 1913.

LETTER TO THE EDITOR.

Some Points for Consideration in Discussing the Reasons Why Some of the Upper Lake Freighters Failed to Weather the Storm on the Great Lakes on November 9th.

Sir,—Now that the first shock caused by the terrible marine disaster upon the Great Lakes of the 9th of November has passed, one can begin calmly to try to think out some reasons for the how and the why. Unfortunately, in all the most important cases not a living soul is left to tell the tale, to lift ever so slightly a corner of the curtain which hides the tragedy, nor to indicate why a number of large steel steamers of modern construction and equipment could not withstand with reasonable safety the force of even such an exceptionally heavy gale as that which sent them to destruction.

It seems almost inconceivable that the "James Carruthers,"* for instance, a brand new ship, which was the product of twenty-five years' experience in steel shipbuilding upon the lakes, beginning with 255-footer and progressing successively through the 300-ft., 400-ft. and 500-ft. classes, until it has reached the modern 10,000-tonner, should disappear utterly, and leave no sign behind to indicate what happened when she took her final plunge into the watery depths of Lake Huron.

A good many possibilities have already been brought forward in the daily papers, and chiefly by practical men, suggesting collision, capsizing through shifting of cargo, want of stability, inefficiency of hatchways, carelessness with regard to hatch fastenings, overloading, deficiency in size, weight and length of ground tackle, stowage of cargo, and want of power, etc., but until an exhaustive enquiry has shown the exact condition of each vessel separately with regard to construction, loading, power,

*For detailed description see *The Canadian Engineer* June 5th, 1913, page 310-11.

nature and quantity of cargo, equipment, draft of water, etc., it is impossible to come to any satisfactory conclusion as to the immediately contributing cause of the catastrophe.

With all available information at hand, it may be possible, by eliminating those conditions which are self-evident, to narrow the enquiry down to such a point as to enable something like a fair and reasonable explanation to be offered in each case as to the cause of the wreck—which is probably as near to the actual result as will ever be attained.

For the sake of humanity, of the shipbuilders, of the owners, of the shippers, and of the insurers, it is imperative that a competent commission be appointed, representing all interests, with power to get at the facts and with ability to draft such regulations as will, as far as it is humanly possible, prevent a recurrence of such a deplorable event.

The loss of life and treasure has been terrible. It would be a still greater calamity if the lessons to be learned by such an enquiry were neglected in any particular whatever.

Whilst it would be premature to discuss matters upon which we have no definite information, there are some phases of the case that can be investigated with propriety from data already made public; such, for instance, as the type of the modern 10,000-ton lake freighter. It would be interesting to compare her with a modern 10,000 gross ton ocean cargo boat, built up to the requirements of Lloyd's Register of British and foreign shipping, and of the British Board of Trade. The leading particulars of the two boats are as follows:

	Ocean boat.	Lake boat.
Length, feet	460	530
Beam, feet	58.5	56
Depth, feet	41.0	31
Draft, feet	27.0	19
Depths to length	11.2	17.1
Drafts to length	17.0	28 nearly
Watertight bulkheads	6	3
Displacement, tons	16,000	15,000
Indicated horse-power	4,000	2,000
Block coefficient	.79	.850
Freeboard, feet	14	12

There are some screen bulkheads in the main hold of the lake freighter, but they are not watertight, and the hold is about 390 feet long, so that if a collision caused any serious damage below water at any point within that cargo space, the vessel's pumps could not keep her free and she would inevitably sink.

These two boats are constructed within a small margin of precisely the same weight of metal, and for a rough-and-ready comparison they may be looked upon as two girders of different dimensions and of equal weight, thus:—

The ocean boat contains 4,750 tons of steel, is 460 feet long, 41 feet deep, and the lake boat with the same weight of material is 530.0 feet long and 31 feet deep. It is evident from this that there is a vast preponderance of longitudinal strength in favor of the ocean boat, which is a point worth considering. This does not prove that the lake freighter is too weak for her work, but if the waves are so much worse for the ships on the lakes than they are on the ocean, as Captain Inkster intimates in his letter to the press upon this subject, one would naturally suppose the preponderance should be the other way. Fortunately, this point can be readily settled, after the plans and specifications have been examined and strength curves made showing the stress upon the materials. These possibly have already been worked out. Lloyd's Rules provide only for normal ships having a maximum length of sixteen depths measured from the keel to the middle deck, or 13 depths measured from keel to gunwale, and even in the latter case, a substantial deck house must, in all cases, be erected extending over half the vessel's midship length. When classification is required for vessels outside or beyond these proportions, special designs have to be prepared and submitted to the committee for their approval, showing how the additional longitudinal strength required is to be provided for.

It is clear that the lake freighter does not begin to measure up to the standard set by Lloyds' for a first-class cargo steamer in this respect, and it cannot be an unreasonable question to ask whether her abnormal proportions of 18 depths to length, with 31 hatchways, each 36 feet wide and 9 feet long, have been adequately provided for so as to enable her to efficiently perform the work she has to do.

Then, as to power. Captain Bassett, in his evidence in the "Wexford" case, stated (according to the press) that "most steamships have sufficient power in relation to their size, although the longest boats would sometimes fail to get headed into the seas if they got in the trough of the seas, because of the tremendous leverage of the boats."

This is a significant statement, coming from such an authority as Captain Bassett, especially in view of the fact that the ocean steamer carries 4,000 i.h.p. and the lake boat only 2,000 i.h.p. The position of the machinery indicating this power is amidships, or nearly so, in the ocean boat, and as far aft as it can be placed in the lake boat. The latter arrangement, of course, leaves all the room forward available for cargo, but it militates against the vessel's seaworthiness—when light, in consequence of her excessive trim by the stern, and at all times owing to the absence of the watertight bulkheads which would have to enclose the machinery space if the latter were amidships.

As regards stability, the ocean boat has a metacentric height of 1 ft. 6 in. at 27 ft. draft with a full load and homogeneous cargo, which would indicate an easy, slow-rolling boat very comfortable in a sea way. The lake boat probably has a metacentric height of something like four feet when full loaded with homogeneous cargo to 19 ft. draft, which indicates ample, if not excessive, stability, but a hard, fast-rolling boat very uncomfortable in a sea way.

When loaded with 10,000 tons of wheat, coal or ore the boat would not be near full, consequently her centre of gravity would be lower and the distance between her metacentre and centre of gravity would be increased proportionately. If, in this condition the cargo should shift heavily, of course it is possible that at a large angle of heel the stability would vanish and the ship capsize, but this is another point that can be cleared up by stability curves made from the drawings of the ship.

It may be asked: Have not the steamboat inspectors power to prevent such vessels proceeding to sea without the proper means for preventing the cargo from shifting, the same as they have for preventing the overloading of passenger steamers? The answer is: There are no de-

tailed regulations in Canada, as yet, for the guidance of inspectors giving them authority over the design, construction or operation of steamers, nor does any competent central body exist, having similar functions to the British Board of Trade, to control marine matters, and to which they could refer in case of necessity. The present inspectors have a very large territory to cover, have an arduous duty to perform, especially during their busy season, and could not possibly be looking after ships on Lake Erie or Lake Ontario, when similarly engaged on the Georgian Bay. They are painstaking and strict in the performance of their existing duties, which they are well qualified to perform, but in the interests of the community at large, the system should be extended. The Canadian merchant marine has become of sufficient importance within a generation to demand a classification of its own, endorsed and supported by government authority.

The pending enquiry will probably result in a coroner's verdict, and it is to be hoped that a trial will be held under competent legal and technical auspices as already indicated.

W. E. REDWAY,
Naval Architect.

Toronto, Nov. 29th, 1913.

STORM SEWERS FOR LONDON, ONT.

A REPORT has recently been submitted to the mayor and council of the city of London by Willis Chipman, C.E., civil and sanitary engineer, of Toronto, upon a system of storm sewers. The city, with a present population of 49,000, has felt for some time the necessity of such a system for the prompt removal of rainfall from its streets. The improvement of roadways and the paving of streets are examples of municipal work that have been seriously held up, pending action in the matter of storm sewers, while the menace to public health through the only existing alternative of connecting into the sanitary sewers to relieve surface flooding has become grievous, owing to cellar and basement flooding by the forcing back of sewage by storm water.

The following information respecting the conditions that have developed during the past twenty years are from Mr. Chipman's latest report upon the situation, and his recommendations and estimates for the improvement of these conditions are appended.

The central business section of the city is now served by a system of combined sewers constructed prior to 1892. At various times drains have been laid in the outlying sections for the removal of cellar and street water, without regard, however, to any system; and, at the present time, fully half of the city is unprovided with storm sewers.

Separate System.—For some years prior to 1891, numerous damage suits had been entered against the city by riparian owners for pollution of the river by sewage which was then discharged into the south branch of the Thames River. Wastes from factories, canneries, and other drains discharged into both branches of the river, and aggravated pollution was the result.

In 1891, Mr. Chipman investigated the problem of disposing of the city's sewage, and presented a report in February, 1892, advising the city to adopt a separate system of sewerage, the domestic sewage to be conveyed by gravity into lands situated west of the city; the sewage from the north area to be collected by an intercepting sewer laid in the valley of Carling's Creek; that from the south area by a similar sewer parallel to the south branch of the river, both interceptors to pass beneath all the existing sewers and to collect from them the normal dry weather flow only. During rains, the interceptors would flow full, the excess passing into the original outlets.

Several tile sewers had been constructed in London South prior to its annexation to the city in 1890. The report referred to recommended a third interceptor for this section.

After lengthy consideration, during which the report was endorsed by Mr. F. X. Goodnough, engineer of the State Board of Health of Massachusetts, and Mr. C. H. Rust, then city engineer of Toronto, the project was eventually adopted by the city council in October, 1896. Construction began that fall and the main sewers were completed in two years' time. In 1901-2, two filter beds were constructed and one sedimentation tank added in 1908-9.

From 1890 to 1913, with the exception of eight streets, storm sewers were not laid with the sanitary sewers, and in the majority of instances the street water was discharged into the small sewers designed for domestic sewage only, notwithstanding the fact that in 1906 it was pointed out by the consulting engineers that the storm water should be rigidly excluded from the latter. The city engineer's department evidently intended to design a comprehensive system of storm sewers, similar to the system of sanitary sewers projected in 1890, but the matter was postponed from year to year, the troubles from storm water constantly increasing.

Catch Basins.—In 1896-97 attention was called to the inadequacy of the "gullies" through which the street water entered the sewers. Each gully comprised a vertical 18-inch sewer pipe or concrete pipe set vertically, with a cast iron grating at the upper end. The earlier form of "gullies" were only 30 inches in depth and 16 inches in diameter, with connections to sewer 8 inches in diameter. About thirty proper brick catch basins, with pits to collect the sand and mud, were built in 1896-99, but since that date the cheap vertical pipe gully that permits the sand, gravel, mud and debris to enter the sewer, has been all but universally constructed. There are now about fifteen hundred of these gullies, as many as twelve being built on one street intersection. The combined capacity of the pipe connections from these gullies would equal the capacity of a main sewer 20 feet in diameter, laid on the same grade as the existing trunk sewer. When it is understood that about fifty gully connections, each running half full, would tax the full capacity of the 36-inch trunk sewer, the folly of discharging the street water into the sanitary sewers can be appreciated.

Drainage Areas.—The total area of the city is now 6,302 acres, while the water sheds of Carling's Creek and other water courses extending beyond the city limits constitute an additional drainage basin with an area approximating 5,000 acres. Mr. Chipman's report recommends the retention of the important natural water courses where practical, as open outlets for the storm water, thus saving the expense of large conduits. A trunk storm sewer is advised for the valley of Carling's Creek, and other storm sewers for London South, Hamilton Road, and Colborne Street. The construction of proper catch basins and the abolition of open gullies are

also recommended. One important measure is that emphasizing the advisability of constructing the storm sewers of at least one year in advance of laying down permanent roadways.

Summarizing the estimate in connection with this separate system, the figures in the report are as follows:

Carling's Creek area	$182,000
North area	28,000
Business area	40,500
Hamilton Road area	46,000
London South area	67,000
London West area	28,500
	$392,000

Sanitary System.—The report also includes some observations relative to the existing sanitary system, the proper maintenance of which is regarded of even greater importance to the citizens of London than the construction of storm sewers. The following remarks are taken from the report:—

"The sanitary system has from time to time been the subject of unfair and often dishonest criticism by the ill-informed public, some of which may possibly be traced back to the battle that was fought in 1896 when the system was adopted, but not without strong opposition. Many citizens cannot divest their minds of the idea that if a sewer be properly designed it should carry anything and everything that can be emptied or even forced into it, regardless of public health or of the cost of the works. Some unthinking people occasionally put forth the contention that the garbage and ashes should be disposed of by discharging them into the sewers. These ignorant opinions still exist, notwithstanding that sanitary engineers and city engineers now recognize and admit that the separate system of sewerage is the only scientific and sanitary system, and at the present day it is being universally adopted in Europe, the United States and Canada. The arguments used against the separate system at London in 1892, 1893, 1896, would not be seriously advanced to-day, and the doubts as to the successful operation of the separate system have been exploded by experience wherever the system has been adopted, particularly so in Canadian cities and towns.

"In 1908 gaugings of the flow in the interceptors demonstrated that they were not then overtaxed and that they were of ample capacity for the domestic sewage flow. In March, 1893, with the ground saturated with water, the north interceptor was found running nearly full, but there can be no doubt that one-half of this flow was due to infiltration of ground water. Portions of this sewer were laid in quicksand beneath the level of Carling's Creek, and as the storm water from the watershed of this stream is not now removed promptly, the subsoil becomes surcharged with water which finds its way into the sewer through leaky manholes and joints in the sewer. By examining these manholes when the water was high, the visible leaks could be marked and the repairs made during dry weather. With the construction of the storm sewer system the normal flow of the interceptors will be materially decreased, but during rains they may run full, as hundreds of 'gullies' are connected with them.

"The inverted syphon that conveys the domestic sewage from the entire city across the Cove flats to the disposal works site has been overtaxed for several years, the excess flow passing directly to the river through the River Street overflow from the Evergreen Avenue chamber. The discharge of crude sewage at this point is continually increasing in volume and will undoubtedly soon cause such a nuisance that litigation will ensue.

"For several years after completion the syphon was sufficient to carry the normal flow, the River Street overflow operating only during rains. As the normal flow increased, the capacity of the iron main was exceeded. It should be mentioned that with a depth of 14 inches flow in the Evergreen Avenue main sewer, the 20-inch syphon would be carrying its full rated capacity. The existing 20-inch cast iron main has a discharging capacity of 3,250,000 gallons per twenty-four hours at the disposal works, or about thirty per cent. of that of the main sewer east of Evergreen Avenue chamber when running full. Another main is required to convey the remaining seventy per cent. for which service a 30-inch pipe should be laid. The Evergreen Avenue chamber, which was never fully completed or equipped, should also be repaired and proper sluice gates provided. The River Street outlet also requires repairs, and improvements, after fifteen years of service. The cost of this proposed 30-inch main, with overflow at the Cove, will approximate $36,000 if cast iron be adopted. Steel pipes would cost about $5,000 less, but their durability is a matter of speculation. It is possible that a reinforced concrete conduit might be constructed at a less cost than cast iron, but the risk would be greater than with cast iron or steel.

"In 1896 the practicability of carrying the main sewer across the river by a bridge to be constructed at King Street was a matter of controversy, but the results have been most satisfactory, the bridge has proven a boon to the city by relieving traffic over the York Street bridge, and no trouble has arisen with the street sewer, supported beneath the roadway of bridge. An inspection of the pipe in March, however, showed that it was seriously corroded, evidently from washings from the plank roadway above, and no time should be lost in thoroughly cleaning the pipe and repainting it, otherwise it will be necessary to replace it at an early date. The sand blast method of cleaning, which is the only thorough method, should be adopted for this work, although the cleaning will cost several times the cost of painting. To lessen, if not to further prevent corrosion, the pipe should be protected by a roof placed above it, beneath the plank roadway, or a concrete roadway substituted for the planking if the trusses are of sufficient strength to support the extra dead load. The bridge and steel trestles supporting the approaches should be also thoroughly cleaned, repaired and painted.

Sewage Disposal.—"The existing disposal works comprise three sedimentation tanks of 200,000 cubic feet combined capacity, and two bacteria beds each with an area of 15,000 square feet. These beds were more or less experimental, and when constructed it was the intention to add others year by year. Funds were not appropriated, however, and the total flow of the sewage was often discharged through the beds. They are now useless except as crude strainers for part of the effluent from the tanks. By removing or washing the filtering materials, the beds may be revived. Whether additional beds be constructed, or spraying filters, or trickling filters, is a matter for careful consideration, but some system should be decided upon before the pollution of the river attains a dangerous or offensive degree. Material alterations should also be made in the three tanks, to convert them into sludge removers rather than sludge digesters, and provision should be made for periodic removal of the accumulations of sludge, without pumping. Beds should also be constructed for drying the sludge."

FIELD EXAMINATION AND TESTING OF CLAYS.

By J. Keele,
Geological Survey of Canada.

FIELD EXAMINATION.

THE testing of any clay or shale for commercial purposes begins with an examination of the deposit in the field. A clay deposit should be conveniently situated with regard to transportation, in a body large enough to keep a plant going for a considerable time, free from harmful impurities, and easily worked. There are many important questions to be considered, however, in the preliminary inquiry, for example:—

1. Can drainage be provided as excavation or mining proceeds, as it is necessary to keep the workings dry?
2. Is the water supply for all purposes adequate and of good quality?
3. If sand is required for mixing, or moulding, can it be obtained cheaply?
4. Consideration of the fuel supply.
5. Are conditions in the locality favorable for labor?
6. Can breakages of machinery be repaired quickly?
7. Can the kiln foundations be kept dry?
8. Would further prospecting reveal a more desirable deposit?

Some idea of the extent of a clay deposit may be gathered in a preliminary way from outcroppings either in plowed fields, hillsides or ridges and along the banks of streams or dry gullies. Springs issuing from hillsides sometimes furnish a clue to the upper level of a bed of clay, as the surface water cannot seep down through it. Wells and foundations excavated for buildings are useful guides; but, railway cuttings often furnish the best information, especially when they are freshly made. As soft clays in a steep bank are liable to be concealed by

Fig. 1.—Deposit of Brick Clay, Without Overburden, Easily Worked.

slide material which has washed down over them, it is often necessary to cut a deep trench up the slope from top to bottom of the deposit before the true character of the beds are seen. Some banks contain several different grades of clay, some of which may be worthless, and so situated as to render the good clay unworkable.

In addition to the information gained from outcrops, it will be necessary to make several borings in order to get at the extent of the deposit and its variations. Borings can be made quickly and cheaply in surface clay deposits with a 2-inch auger, coupled to short lengths of pipe and fitted to a cross-head. The auger is screwed into the clay for about six inches, then withdrawn with a straight pull, and the clay which clings to the auger removed. As the boring proceeds, extra lengths of pipe are added. The clay stripped from the auger is laid out in the proper order on boards or on the grass, from which small samples can be selected at any depth up to 30 feet or more if desired.

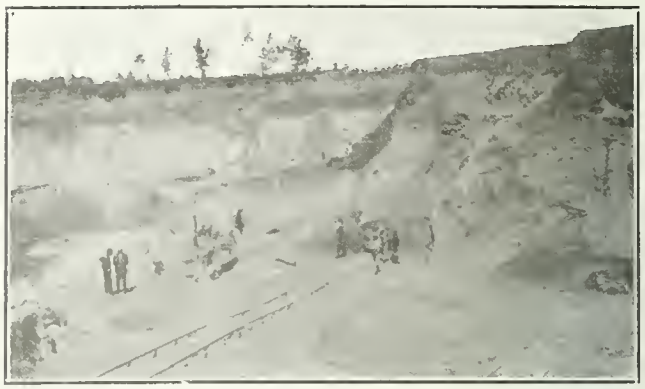

Fig. 2.—Pit Containing Sand, Gravel and Clay, Difficult to Work for Brickmaking.

The clay deposit may be covered with a varying thickness of either gravel or stony clay which cannot be used for any purpose. In most cases it will not pay to strip this overburden if it is very thick; but the higher grades of clay, like stoneware and fire clays, can have an overburden of one foot removed for every foot of clay obtained. If the overburden is composed of sand, much of it may be used for mixing with the clay, especially if it should be a fat clay with high shrinkage. An otherwise useless overburden may sometimes be used for filling or levelling up ground on which it is proposed to erect the plant, or it may be removed cheaply by hydraulicking, if a sufficient head of water is available. An overburden which contains pebbles, especially pebbles of limestone, should be removed completely and kept well back from the face of the bank which is being worked, so that there will be no danger of the pebbles rolling into the material that is being worked for the manufacture of clay products.

Shale deposits are often exposed in fairly steep banks, either in an escarpment or on stream banks or in a railway cutting. From exposures of this kind a good idea of their probable value may often be formed. If the outcrops on the property to be examined are not exposed to any appreciable depth, it will be necessary to sink some shafts before any sampling can be done or any decision formed regarding its economic value.

Several of the soft shale deposits in the plains region of Western Canada can be examined as easily as surface clays from borings with an auger, but the shales in the East are all too hard for this method of sampling.

The shale formation in Eastern Canada are generally uniform in character over very large areas, but those in the West are often extremely variable, so that they require great care in sampling and examination.

Impurities in clay or shale are of two kinds—those which are visible to the naked eye, and those which are not. The field examination detects the first kind, and the laboratory tests should reveal the second kind. Pebbles are probably the most serious visible impurities in surface clays. They may occur sparsely scattered throughout the clay or they may be in the form of gravel streaks, pockets, or regular layers. If the pebbles are mostly of limestone,

the deposit is practically hopeless. Some manufacturers in search of material will not consider a deposit, if they find it contains even a few scattered pebbles. Layers or pockets of sand, if not in too large a quantity, are sometimes beneficial in a surface clay, especially if it is of a highly plastic nature. Brickmakers like a clay bank to work itself, meaning one that carries the right proportion of sand for a proper mixture. An excess of sand layers is undesirable in a clay deposit, because the product made

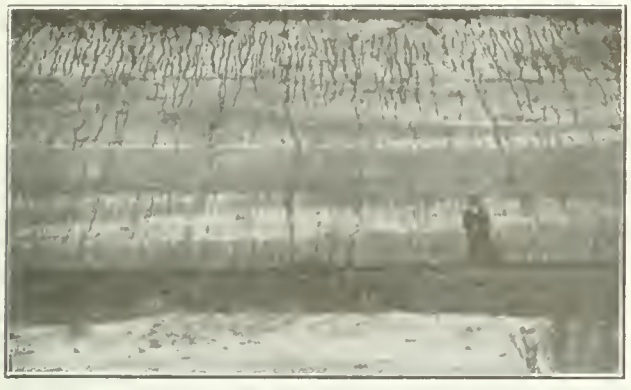

Fig. 3.—Bank of Soft, White Sandstone and Dark Shale These Shale Beds are Unworkable as the Sandstone Overburden is Too Thick.

from it is liable to be weak and porous, or lacking in clay bond. Although a shale deposit may consist largely of beds of true shale, it is possible that it may also contain so many layers of sandstone or limestone as to be of doubtful economic value. If the stone bands are thick enough they may be sold for building stone, if a convenient market exists for them. Ironstone constructions and lumps of iron pyrite are among the serious impurities in shales and clays. They sometimes occur of such large size that they may be discarded in mining. Gypsum or lime sulphate is a frequent impurity in the soft shales of Western Canada. It generally occurs in small glistening particles disseminated through the shale; or it may be in large crystals or rosettes. It generally follows in the west that clays carrying gypsum are hard to dry without cracking.

It is generally impossible to foretell much about the value of a clay or shale by simply inspecting the deposit in the field. An experienced clay worker, however, can gather some information for his guidance in the selection of material. The feel of the moistened clay when kneaded in the hands indicates its degree of plasticity and its probable working qualities. A shale may be distinguished from a slate by grinding a little with a hammer and moistening it. The moistened shale dust will have more or less plasticity, but a slate will have none. Any clay or shale that carries more than about 7 per cent. of lime will probably be useless for the manufacture of vitrified wares, such as paving brick or sewer pipe. If a few drops of diluted hydrochloric acid will produce strong effervescence in a clay it may be discarded as unsuited for this purpose.

Many clays will crack in drying. These can be easily detected by kneading up some of it with water to the proper consistency, shaping it into a rough brick or cube, and setting it to dry exposed to the sun and wind. Some clays thus exposed will crack in less than an hour after being set to dry. Others will not show cracking for several hours. If the clay dries intact, then make another brick by hand and set it over a boiler or in an oven at a temperature of about 150° F., and observe the results. A clay must be able to stand a certain amount of abuse in drying in order to give a large output of finished products.

Since few clay or shale deposits are uniform in character throughout their entire thickness, the selection of samples for testing purposes is a matter of some importance.

If the deposit appears to be uniform, then the sample should represent an average of the depth of the face it is proposed to work. The average sample should be supplemented by two or three other samples taken from different depths, as appearances are frequently misleading in clay investigation. Many persons pick a small sample of clay from the surface of a deposit and send it to be tested. The results of tests from this kind of sampling are generally useless. The body of material, when opened up for working, may give entirely different results from the thin veneer of weathered clay overlying it. In a locality where industries have been located for a long time, working satisfactorily on a material which occurs widespread and uniform in character, the necessary information may be obtained merely by inspection of a suitable site in the vicinity of the older plants. This proceeding is often, but not always, safe where the manufacturer of common brick only is concerned. Where any of the higher class of clay products were to be made, the cheapest method is to take every possible precaution at the outset of the enterprise.

Laboratory Tests.—The invisible impurities in a clay, which may produce defects in the process of manufacture or in the appearance of the finished ware, can be detected only by working up and burning test pieces made from the clay.

A good deal of time and money has been expended on the chemical analysis of clay, and many chemists have been rash enough to state in reports the kind of wares

Fig. 4.—White Clay in Central Alberta, Overlain With Worthless Shale.

a clay will make, from the results of their chemical analysis alone. There may be special instances, as in the case of some high-grade clays, where the chemical analysis is of value, but is is worthless for the general group of clays or shales used in the manufacture of structural ware.

What the clay worker desires to know about a clay or shale is:—

1. Its plasticity and working qualities.
2. The rate of drying.
3. The exact drying and burning shrinkages.

4. The commercial limit of burning.

5. The porosity and absorption of the burned wares.

6. The actual difficulties encountered in burning, such as cracking, warping, or swelling, and scumming or whitewash.

Many of the important clay-working plants in the United States and England, especially those making a variety of wares, have an experimental laboratory, with small kilns for burning trials in charge of a competent ceramist. These firms test a large number of clay samples which are sent to them from outside sources. Three or four of the State Universities give courses in Ceramic Engineering, and have very fully equipped clay-testing laboratories. A certain amount of commercial work is done, for which fixed charges are made according to the scope of the investigation. The tests are conducted by experienced men whose reports are reliable and extremely valuable to the person or company about to start a clay-working industry.

Most of the manufacturers of clayworking machinery have a clay-testing department on their premises. These people invite prospective customers for machinery to send samples of their clay and have it worked up into specimens of ware. They generally make the tests free of charge. The specimens of burned wares sent back by the machinery companies to their prospective customers are generally perfect in every respect. These samples should be regarded as a standard to be ultimately attained to, however seldom reached, in the everyday world of clayworking.

Tests Under Working Conditions.—If a company or individual wishes to establish an important clayworking industry at a certain place to make a certain class of wares, a reasonable way to proceed in the tests of their clay, provided the field examination was satisfactory, is as follows: Take an average sample of, say, 50 lbs. from top to bottom of the workable depth of the deposit, if it is uniform in appearance, or as many samples as

Fig. 5.—Shales along Red Deer River, Near Lignite, Alta., Overlain by Too Much Boulder Clay.

there are different beds. Have a complete set of laboratory tests made from the samples. If the laboratory tests prove satisfactory, then make arrangements with some firm, outside the zone of competition, who are making wares similar to those required, to put a large quantity of clay through their process and to burn it in their kilns. It is important to have an experienced man do the sampling and accompany the clay to its destination, so that he may observe the behavior of the material in the various stages of manufacture.

The proper location of the deposit and the assurance of the suitability of the clay for the purpose for which it is to be used, are absolutely essential to begin with.

The plan of the buildings, the design of the kilns or driers and the selection of the best types of clay-working machinery, should be done by a competent ceramic engineer.

It is impossible to provide against all the troubles which may arise in new localities when dealing with a new material; but the chances for the occurrence of trouble can be materially lessened by proper precaution.

Fig. 6.—Stratified Brick Clay Deposit, Overlain by Too Much Sand.

The business of manufacturing clay products is a desirable one in many respects. It gives healthy employment and produces articles of great use to a community. It is a fairly profitable business when brains and technical skill, as well as capital, are invested in it, varying nowise in this respect from any other complex producing business. It is just as easy, however, for the unwary novice to lose his money in a homely looking clayworking plant as it frequently is in the more spectacular operations of metal mining.

Work of the Geological Survey.—The Geological Survey has carried on a systematic investigation of the clay and shale deposits of the Dominion since 1909. The reports that are published at intervals contain complete results of laboratory tests, together with descriptions of the field occurrence of the materials collected. They are intended as guides for manufacturers in search of material, but are of general interest to all clay workers.

PEAT POWDER AS A LOCOMOTIVE FUEL.

Peat powder has been successfully applied as a locomotive fuel on one of the private railroads in Sweden. In steam raising value about 1½ tons of peat powder is equivalent to one ton of coal. Peat powder is used with a mixture of about 5 per cent. of coal, and is fed into the furnace by an automatic stoker. No change need be made in the boiler end in the fire-box, except for the mounting and application of the automatic stoker. An incidental advantage of the use of the peat powder is that no cold air can get into the fire-box and no smoke or sparks escape from the smoke-stack. As Sweden is very rich in peat bogs, and has practically no coal deposits, the success of the apparatus, which has been worked upon for years by eminent engineers, is of considerable importance. It has been estimated that the cost of peat powder would be only about one-half that of coal.—Conservation.

A DINNER IN HONOR OF DEAN GALBRAITH.

ON Friday, December 5th, the University of Toronto Engineering Society held its 25th annual dinner. This year it took the form of a re-union in honor of Dean Galbraith, the founder of the School of Practical Science, known for some years past as the Faculty of Applied Science and Engineering in the University of Toronto. Nearly six hundred engineers were in attendance, and the principal centres of Canada and the United States were well represented. Mr. F. C. Mechin, president of the Engineering Society, acted in the capacity of toast-master, and during the progress of the evening read innumerable letters and telegrams expressive of the profound regret of many prominent graduates in far away localities who found it impossible to attend.

As stated, the dinner was in honor of the Dean of the Faculty, and every toast, together with its response, reverted to his profound patience and unceasing perseverence in the building up of the institution which has broad-casted throughout the world nearly fifteen hundred men whose good fortune it was to partake of the advantages which his training in fundamental principles afforded to them. Many were the reminiscences which at one time or other during the evening ascended bouyantly to the surface and illustrated the spirit which dominated the engineering course since it was founded by John Galbraith thirty-five years ago.

President Falconer, in response to the toast "University of Toronto," outlined the remarkable influence of Universities upon the national life in Germany and other countries, as evidenced by the strenuous activity of these countries in the progress of the world. In this connection he referred to the evidences of spreading influence of the University of Toronto as shown by a recent trip through the Canadian West. The president referred in most kindly terms to Dean Galbraith and the regard in which he was held at the University, pronouncing him as the man who, above all others, had made possible in the engineering faculty of the University an atmosphere of integrity and cleanliness of character yielding results of untold value to this Dominion.

Col. W. M. Ponton, of Belleville, in an interesting response to "Canada," mentioned numerous instances in the career of Dean Galbraith indicative of his personality, his potentiality, and his position in the regard of men outside of the University and in other professions. His closing sentence related to those assembled, in the following terms: "Looking upon this throng that has assembled to honor Dean Galbraith, some of you from great distances and with much inconvenience, I cannot but admire your spirit of loyalty to the man who instilled into you those first principles of character and thought, and I can see in my mind's eye hundreds of others of the School graduates in all parts of the earth regretting with heartfelt sorrow that they cannot be with you to do honor to their Dean."

A toast to the "Profession" was responded to by R. A. Ross, Consulting Engineer, Montreal, a graduate, '91, and H. F. Ballantyne, '93, a prominent architect of New York. Mr. Ross referred to the preparatory importance of the University course in fitting a man for the profession of engineering. He noted the various ways it which the public regarded the profession in general, and intimated in this connection that possibly the engineer did not take the place in public life that he should, suggesting that too much work and too great a devotion to his own particular field, might be the cause of the engineer's shortcomings in the matter of participation in public affairs. The broadening field of engineering leading as it now does to administrative work and to positions on commissions was in itself an indication of the necessity for an exceptionally broad training for the engineer of the future.

Mr. Ballantyne's tribute to the profession centred chiefly about the Dean, and he dwelt briefly upon the remarkable appreciative manner in which the engineers of prominence in the city of New York regarded him and his work.

John Galbraith, M.A., LL.D.,
Dean, Faculty of Applied Science and Engineering, University of Toronto.

Dr. Galbraith, in responding to the toast given in his honor, dwelt reminiscently upon his early experiences at the University, which he entered fifty years ago as a student, his object being to learn engineering. Much to his surprise, he found that although the University assigned examinations and awarded diplomas in engineering in 1863, no actual instruction was given. Hence, he enrolled in Arts.

In 1878, he undertook the task of teaching engineering. This was the beginning of the "School." From 1878 to 1889, Dr. Galbraith and Dr. Ellis, assisted by professors in Arts, gave all the instruction. The Dean pointed out that his first assistant was Mr. G. H. Duggan, a graduate of 1883, now vice-President and Chief Engineer of the Dominion Bridge Company, who was present at the meeting.

Dr. Galbraith pronounced the graduates of thirty years ago to be as well trained as are our present graduates. The course of training given at that time equipped a man for the responsibilities of his work as fully as does the present curriculum, the difference being in the scope of the engineering field now as compared with thirty

years ago. He stated that his long experience indicated that the system of training engineering students in the University of Toronto compared very favorably with the systems which obtain in the other great Universities of the world.

This brief summary of the prominent features of the event does not serve to illustrate in any manner the general feelings of loyalty, appreciation and gratitude, which accompanied every remark and every occurrence throughout the occasion. From the first graduate of the School who left its halls in 1881, to the men who anticipate graduation ceremonies in 1917, it is sufficient to state that practically all years were represented, and that almost every city in the Dominion sent its quota to participate in an event to honor Dean Galbraith.

HANDLING SHIPPING IN PANAMA CANAL

Development of plans for meeting the demands of shipping in the Panama Canal in the way of terminals, coaling stations, warehouses, wharves, dry docks and repair shops, are outlined in the report to the war department of the Isthmian Canal Commission for the year ended June 30 last. The report was prepared by Colonel George W. Goethals, chairman and chief engineer of the Corps of Engineers, U.S.A.

Terminal facilities for shipping, the report states, cannot be completed by the time the canal is ready for passing vessels. The reason for this is the fact that the authorization for preparing such facilities was not made by Congress till August 24, 1912, and active operations could not be begun until the fall of that year.

The Pacific terminals which are being constructed by the commission, will consist of a main dry dock capable of docking any vessel than can utilize the locks, a smaller dry dock for use of smaller craft, a plant for supplying coal and fuel oil to vessels, the necessary wharves and piers for commercial purposes, and the permanent shops for use in connection with the dry docks.

The Atlantic terminals consist of wharves and piers at Cristobal, including the Cristobal mole, all of which are being constructed by the Panama Railroad at its own expense, and the main plant for supplying coal and fuel oil to vessels. The cost of the coaling plant will be divided between the commission and the railroad, while the commission will furnish facilities for oil.

Numerous applications, the report states, have been received from coal dealers for loading space for the handling of their coal in supplying vessels that will use the canal. In order to encourage the business of furnishing coal to vessels which use the canal, the policy has been adopted of providing storage in connection with both coaling plants for the coal piles of individuals and companies who desire to participate. It was never intended that the government should exercise a monopoly of the coal business on the Isthmus, but to utilize the coal stored there for the use of the navy in maintaining uniform prices of this product to shipping. There will be a certain rental charge for the areas occupied by the coal dealers, and, in addition, a real estate tax of 1 per cent. of the value of the improvements, should any be made, and a merchandise tax of 5 cents for each 2,000 lbs. of coal sold.

The government will attend to all the handling and charges for putting the coal into storage and taking it out; charges for the use of coal barges, and other labor in connection with this service will be fixed at cost price to the government for such service.

ARMSTRONG, WHITWORTH'S NEW CANADIAN PLANT.

PROMINENT among recent additions to Canada's home industries in the metal trades, is the new plant of Messrs. Armstrong, Whitworth of Canada, Limited, now nearing completion at Longueuil, Quebec, across the river from Montreal. Readers will recall a reference to this new industry in June 19th, 1913, issue. The parent English company, of Sir W. G. Armstrong, Whitworth & Company, Limited, with its several huge plants, is one of the oldest and largest manufacturers of high-speed crucible tool steel in the world. The new

Fig. 1.

Canadian plant profits from this experience, commencing its operations with the advantages of equipment and processes that have been found desirable by the older company. It will manufacture high-grade tool steel, including the "A.W.," "T.Y.R." and "A.W. Premier" brands, drills, reamers, cutters, taps and dies, machine tools, cranes, forgings, lock and dock gates, etc.

With complete equipment for the manufacture of these standard lines, and also of special steels where re-

Fig. 2.

quired, and with production capacity large enough to supply all reasonable requirements, the new plant will supply a real need in the Canadian metal trades. It is the company's intention to carry a complete and ample stock of standard lines, so as to insure quick deliveries.

The plant itself embodies the most modern ideas, in layout, construction and equipment. The accompanying illustrations give partial views of the main building, which is located near the main line of the Quebec, Montreal and Southern Railway. A siding was run in alongside of the building and continued to the water-front. Another siding runs along the north side of the building, and a third siding into the building. The total length of all sidings is approximately a mile. The building itself is 500 feet long, 175 feet wide at one end and 100 feet wide at the other end, with a boiler house separate from the main structure. It is of steel construction, with reinforced concrete walls and roofs, except on the north side, where the walls are of timber with metal lath and plaster, thus providing for future extension of all departments, seven in number, in this direction. Both by reducing the size of pilasters and cornices to the medium width, having due regard to strength, and by means of monitors and skylights, all the different departments have been made as light as possible.

Practically all of the foundations are on solid rock. A trench 5 feet wide and from 7 to 14 feet in depth was run from the main building down to the water-front, where the pump-house has been built. This trench contains a 24-inch vitrified clay pipe for water discharge, and an 8-inch cast-iron water pipe for the plant's water supply, provided by electrically driven centrifugal pumps. Underneath the pump-house, a concrete-lined pit was sunk to a depth of 6 feet below the lowest known water level of the St. Lawrence River. From the bottom of this pit, a tunnel lined with heavy timbers was run under the water-front road and from the point at which it emerged on the shore, a trench was dug for a distance of about 300 feet out into the St. Lawrence River. In this trench an intake or crib was built—the end being 5 feet below the lowest recorded level. This insures a continuous supply of water to the pump-house at all times of the year. As the formation in the bottom of the river was hard-pan, the trench was taken out without any sheet piling being used, the excavation from the trench being piled up on either side, thus forming a dam to prevent the trench being flooded. No seepage into this trench took place. A sludge gate is provided on the river side of the pump-house, so that the intake of water may be shut off at any time.

Wonderful turbines will drive the mammoth Cunarder Aquitania, which is now being completed at Clydebank. They have a total weight of 1,400 tons, and to enable them to be lowered into the hull of the ship, one of the four great funnels could not be placed in position. There are more than a million turbine blades, the combined length of which is more than 140 miles. The blades vary in length from one and a half to twenty inches. These turbines are absolutely the latest production of marine engineering.

In a lecture given in Berlin, Germany, before an audience consisting largely of electricians, Herr Reiss, an engineer, described an invention by which he claimed that the range of the telephone will be enormously extended. He stated that with the apparatus, which consists of a new form of relay, conversations over 2,000 kilometres can be heard with as much distinctness as those held over half that distance at present. It would appear that all the financial and other preparations have been made by big electrical companies here for putting the invention on the market without delay.

RESISTANCE OF STEEL TO WEAR.*

By George L. Norris.

THE increasing speeds and heavy duty of machinery and motive power with resultant shortening of length of service of parts through rapid wear, makes the study of wear-resisting qualities of metals, especially steel, one of increasing importance. In the railway field, the increasing wear of tires and rails due to increased loads and speeds is a serious problem. Not only is it desirable to have high resistance to wear, but it is necessary to have other qualifications, strength and toughness, to insure against failure or breakage. The tests described in this paper were undertaken with the object of studying the relations, if any, between the wear resistance of various steels and the various physical properties of elastic limit, tensile strength, and hardness. Owing to several protracted interruptions, only a relatively small proportion of the tests projected have so far been completed.

There are three classes of wear:—

(1) Abrasion, such as grinding, to which crushing and extracting machinery is subjected.

(2) Lubricated sliding or rolling friction; such as that to which machine parts, axles, shafting, etc., are subjected.

(3) Dry rolling friction, to which wheels and rails are subjected.

The first class, wear by abrasion, is in many ways less important than the other two. It has, however, been utilized frequently as a means of comparing the wearing qualities of metals for all three classes. The machines for the purpose are some form of grinding machine and the specimens are ground or abraded under a constant pressure for a certain length of time.

The signs of wear by lubricated friction in the past have been largely confined to bearing metals rather than steel. This has been due undoubtedly to the fact that steel is usually worked against soft bearing metals or bronzes. The investigation of the wear resistance of steel and iron under lubricated friction, however, is growing more important with the increasing severity of the requirements of service. Probably the most satisfactory device for testing wear under lubricated sliding friction is the Derihon machine, consisting of a hard steel disc revolving in oil, and against the edge of which is pressed the test specimen.

The third class, wear by dry rolling friction, is the most important, especially when we consider the vast tonnage of steel in service in the form of rails, wheels and tires.

A machine for investigating wear under dry rolling friction was described by Mr. E. H. Saniter in 1908, before the Iron and Steel Institute, and consists essentially of a revolving test specimen which drives by friction the inner ring of a ball-bearing, the outer ring of which is stationary and loaded.

The investigations of the author have been confined so far to the third class of wear, dry rolling friction. The machine used is a modification of Dr. Stanton's fatigue-testing machine. This machine consists essentially of three case-hardened rollers, 3½ in. in diameter. The two lower rollers are driven by gears, while the third, upper

*From a paper read at the Atlantic City meeting of the American Society for Testing Materials.

roller, is driven by friction. The upper roller is carried in the lever by which the load is applied to the test specimen. A load of 1,000 lbs. on the specimen is possible with this machine. The rollers each have a groove in the middle, ¼ in. wide, to take the corresponding band on the test specimen and to keep it from lateral motion. If the rollers all revolved at a uniform speed the amount of wear on the test specimen would be very slight, practically nothing, as there would be no slippage of the test specimen. In order to accelerate the wear and approximate as nearly as possible the actual wearing conditions of wheels and rails, the two lower rollers are driven at different speeds to produce a slippage of the specimen. This is accomplished by having two less teeth in one of the driving gears.

The test specimens are 2 in. long and ⅞ in. in diameter; the guide hand is ⅛ in. larger in diameter and a scant ¼ in. wide. They weigh about 160 grammes, and can be accurately weighed on a chemical balance to 1/10 of a milligramme. The diameter of the specimens which this machine will take can vary from ⅝ in. in diameter to 1½ in. in diameter, if desired. The driving speed of the machine is 1,000 r.p.m., and the speed of the test specimen is about 5,000 r.p.m.

The usual run before weighing is 100,000 revolutions of one of the driving rollers, corresponding to practically 500,000 revolutions of the test piece. In the tests included in Tables I. and II., the applied load was 224 lbs., or 100 kilograms; except in the cases noted in Table I., the specimens were all turned from rolled bars, 1⅛ in. in diameter.

While the tests show a general decrease in the amount of wear as the hardness and strength increase, the progression is irregular, and there are several instances where softer steels show less wear than the harder ones, as for example 12 and E-1; C-1 and F-1.

It is evident that the composition of the steel influences the resistance to wear to a considerable degree. Robin, in his investigations, found that nickel, chromium and vanadium each increased the resistance of the steel to wear. Nusbaumer in his tests found remarkable resistance to wear in low-carbon tests with manganese about 1.5 per cent. Saniter, on the contrary, did not find increased resistance to wear in the case of the few alloy

D-1	230.1	340	52	156,000	161,150	16.0	53.3	825/600

steels he reported, except for a high-manganese steel of the Hadfield type. His chrome-vanadium and nickel-chrome steel gave greater wear with greater hardness than simple carbon steel of about 0.70 per cent. carbon and 0.60 per cent. manganese.

The tests which I have made confirm the conclusions of both Robin and Nusbaumer, and also those of actual service experience, that manganese, nickel, chromium, and vanadium have a marked effect on the wearing qualities of steels. Manganese apparently has a greater effect than either nickel or chromium. Vanadium, however, evidently has a much greater effect than either of these three elements, as it only requires a very small percentage to produce a marked increase in resistance to wear. This is apparent in steels E-1 and F-1; and C-1 and D-1, each of which pair is practically alike, except for vanadium. These tests are only a small proportion of those planned, and it is the intention to cover not only a considerable range in composition and heat treatment, but also to study the effect of rollers of different composition and hardness, on the rate of wear of the various steels.

STRUCTURAL MATERIALS AND CLAY PRODUCTS

The following is a statistical table of structural materials and clay products as contained in the Economic Minerals and Associated Industries, by J. McLeish, Chief of the Division of Mineral Resources and Statistics, Canada:—

Product.	Quantity.	Value.
Cement, Portland .....Bls.	7,132,732	$ 9,106,556
Clay products: ($10,575,709)		
Brick, common .....No.	769,191,532	7,010,375
" pressed ..... "	125,180,422	1,609,854
" paving ..... "	4,579,500	85,989
" moulded and ornamental ..... "	371,356	8,595
Fireclay and fireclay products.	.....	125,585
Fireproofing and architectural terra-cotta	.....	448,853
Pottery	.....	43,955
Sewerpipe	.....	884,641
Tile, drain	.....	357,862
Kaolin .....Tons.	20	160
Lime .....Bus.	8,475,839	1,844,849
Sand-lime brick .....No.	96,448,402	1,020,386
Sand and gravel (partial record)..	.....	1,512,099
Slate .....Sq.	1,894	8,939
Stone: ($4,726,171).		
Granite	.....	1,373,119
Limestone	.....	2,762,936
Marble	.....	260,764
Sandstone	.....	329,352
Total	.....	$28,794,869
Grand total	.....	$135,048,296

Work was begun Nov. 5th on the one thousand foot pier in the Hudson River at Forth-sixth Street, that marked the beginning of harbor improvement which it is claimed by its initiators will place New York on a par in accommodations for shipping with the great harbors of the world. Other piers of equal length are planned, and eventually the entire Hudson River waterfront, city officials predicted to-day, would be re-built for the accommodation of the great ocean liners of the future.

COAST TO COAST.

Hamilton, Ont.—About one mile of Hydro street-lighting has recently been turned on in Hamilton on Barton Street.

Vancouver, B.C.—Preliminary work on the overhead bridge to be erected by the C.P.R. to produce Granville Street to the waterfront is well advanced.

Regina, Sask.—The report of Superintendent Venzke, of the civic Parks Department shows that 8⅓ miles of new boulevards were graded last year in Regina.

Moose Jaw, Sask.—Another street car service has been formally opened in Moose Jaw, e.g., the car line built to Boulevard Heights, about two miles from the centre of the city.

Ottawa, Ont.—It is stated that the surplus over operating expenses on the I.C.R. will exceed this year by a considerable amount the million dollar mark. Last year's surplus did not attain the million mark; but since rates have been raised, and traffic has increased.

Owen Sound, Ont.—Owing to an extraordinary expenditure upon bridges during the past year, the County Treasurer, Mr. S. J. Parker, has stated to the Council that, in his opinion, the treasury will show a deficit of about $10,000 at the end of the year.

Regina, Sask.—In the recent report made by Superintendent McKay, of the Waterworks Department, it is shown that 101,281 feet of water pipe have been laid under contract during the last ten months, and 2,941 lineal feet of pipe by day labor, making a total length of pipe laid in the city of 104,222 feet, or approximately 20 miles.

Ottawa, Ont.—The last connecting rail has been laid between Quebec Bridge and Yellowhead Pass, no particular ceremony being connected with the event. Though the laying of steel is by no means the final act in completing a line, authoritative information has been given to the effect that when traffic at Winnipeg is offered, the railway will be able to handle it.

Regina, Sask.—The Waterworks Department has shown very economical management during the past year, $17,000 less than the estimated amount of $59,670 having been expended. The estimated capital expenditure of $546,178.70 was also in excess of the actual expenditure of $496,082.06. The operation of the waterworks system showed a profit of $57,327.33, which gives a net surplus of $4,570.69 after debenture charges are deducted.

St. Catharines, Ont.—During the year thus far, building permits of approximately three-quarters of a million dollars have been granted in St. Catharines. A like amount has been expended on local improvements. The expenditure on new constructive work during 1913 will thus be in excess of $1,500,000 within this city; and on the new Welland Ship Canal construction in close proximity to the city, contracts amounting to $34,000,000 have already been let.

Le Pas, Man.—The first trial of the receiving instruments at the wireless station signals has been made, and Operator E. Richards reports signals obtained from Sayville, N.Y.; Arlington, near Washington, D.C.; Cape Cod, Mass.; Glace Bay, N.S.; and also from the stations on the Pacific Coast of the United States; so that this station can hear what is transpiring at both sides of our continent. The signals from all stations on the lake shores can be distinctly heard, and also from most of the boats on the lake.

Fort William, Ont.—The excavating of a tunnel under the main building of the Canadian Car and Foundry Company in connection with the construction of Stanley Avenue sewer has been commenced. The tunnel must be driven approximately 160 feet under the building, and a shaft will have

to be sunk in the centre of the floor of the building which will allow four gangs of men to work simultaneously, two gangs at the bottom of the shaft, one working west, the other east; and two gangs, one at either end of the tunnel working centrewards.

Victoria, B.C.—Several small forces of men are already engaged on the north-west sewer construction at different points along the ravine which runs from Burnside Road down to the Gorge Road and thence to Selkirk water. Arrangements with the C.N.P. Railway for the right-of-way are expected to be successfully concluded so that no delay or postponement of the work will be occasioned, and so that the whole work may be opened in this section in a short time. The next section of the undertaking to be commenced will be the Esquimalt section; and on this excavation work will be more difficult, owing to the more rocky nature of the district.

Estevan, Sask.—The experimental plant at Estevan, which the Saskatchewan Government has just lately finished erecting for the purpose of determining the exact value of lignite coal for power purposes, briquetting, etc., is in operation under the management of Mr. S. M. Darling, a well-known expert, under whose supervision the plant has been erected. Mr. Darling has shipped a car of "carbonized lignite fines" to Cape Breton, where this product will be tested as a powdered fuel in the Bettingen boilers of the Dominion Coal Company's plant. The larger sizes of the carbonized lignite it is the intention to use in gas producers to generate electrical energy, and in chain grate furnaces for steam power. It is expected that the result of these tests will solve the power problem of Saskatchewan.

Regina, Sask.—Good progress on the power house under construction at Regina has been reported by Superintendent Bull. The building walls, machine foundations, and a small part of the floor in the boiler-room of the new power house have been completed. Partial equipment of machinery boilers and piping is awaiting installation; and it is hoped to have sufficient equipment to operate the first 1,500 k.w. machine installed and housed under a temporary wood building by Christmas. The output of the plant for the past ten months has been 6,017,610 k.w. hours, while for the corresponding ten months of 1912 it was 3,186,938, which shows an increase of 88.8 per cent. The capital expenditure for the ten months was as follows: on the new power house by-law, $132,418.71, of which $18,994 has been in wages; on the by-law for electric light and power extension, $129,589.71, of which $16,688.10 has been paid in wages.

Vancouver, B.C.—Eight of the nineteen steel bridges on the British Columbia section of the Canadian Northern Pacific Railway have been completed, and are available for traffic. Of the remaining eleven, three are at present well under construction, and another has been commenced near Jackass Mountain, 126 miles east of Port Mann, at the present end of steel. One of the three bridges is at Lytton, where the C.N.P. line crosses the Fraser River a mile below the town. It will be 870 feet long, and will be constructed with four plate girder spans and three deck truss spans. Its foundations have been completed, and its superstructure well advanced. A 250-foot viaduct is being constructed in the Black Canyon, 189 miles east of Port Mann, and will be a 210-foot through truss span with a deck plate girder. At mile 81 on the section of the C.N.P. north of Kamloops, a 600-foot bridge is being erected over the North Thompson River at Birch Island, which will have seven spans. Late reports from the engineers in charge state that four of the spans have been placed, and traffic is being handled over the river to mile 90, the present end of steel, by means of a temporary structure.

Regina, Sask.—City Engineer McArthur has furnished a report of the works completed by his department during the past year. A total area of 140,288.5 square yards of pavement at a total cost of $481,372.12 have been laid. Of this area, 80,874.8 square yards are bitulithic; 58,922.6 square yards, sheet asphalt; and 421.1 square yards, Westrumite. The length of pavement would be about 8 or 9 miles, though the width for residential streets is 24 feet, and otherwise 32 feet. The total length of sewers laid in the city, including the work done on the contracts of the previous year, was 96,936.3 lineal feet, or approximately 18½ miles; and the total cost, $553,731.84. The total current expenditure of the department, which includes repairs to pavements, walks and sewers, street grading, street cleaning and salaries, was $85,174.65, which was about $7,200 over the estimated expenditure for this department. The total expenditure of all the work carried on under the department during the ten months totalled $1,226,939.36. The total engineering expenses, including salaries for the entire staff and inspectors and all office expenses and supplies, came to $23,643.68, being less than two per cent. of the cost of the work.

Calgary, Alta.—City Electrician Brown submitted on November 27th to Commissioner Graves a report on the estimated receipts and the expenditures for the municipal electric department. The total estimated revenue is given as $575,000; the total estimated expenditure, $545,053.01, leaving an estimated surplus of $29,946.99. Commissioner Graves proposes to use this surplus to help pay for the placing of wires underground. Electric light and power rates are now very low in Calgary, and placing the wires underground will add both security and an improved appearance to the city. An approximate estimate of the required electric light extensions for 1914 was also furnished to the commissioner by Mr. Brown. Approximate costs for these amounted in all to $350,000, the money to be secured by the customary by-law.

Kamloops, B.C.—Recently the Hon. F. W. Aylmer, Dominion Government engineer at Chase, had a conference with City Engineer Wilson, of Kamloops, concerning the proposed wharf extensions and promenade along the Riverside Park waterfront. It is expected that the government may consider, in addition to what it will be asked by the city to undertake in the work the erection of a permanent concrete wall along the waterfornt of Riverside Park and the dredging of the river, leaving the city to complete the decking, etc. This would give Kamloops one of the finest river wharves in the Dominion, besides affording easy and safe navigation to steamers at all stages of the water, as well as providing a park promenade and "embankment" that would be well in keeping with the ornamental plans of Riverside Park, as approved by the city, and a magnificent river frontage that would be second to none in the West.

Vancouver, B.C.—Mr. M. Swan, M.I.C.E., M.I.M.E., M.C.S.C.E., at one time engineer for the Montreal Harbor Board, and recently returned from South America, where he has been engaged as a government consulting engineer, has made a personal inspection of Vancouver harbor, and also the sites of harbor projects for Greater Vancouver, and has submitted a report to the Vancouver Harbor Commission. He states that Vancouver has in embryo the finest harbor in the world, and that no expense should be spared in developing it and providing proper facilities. He emphasizes the necessity of securing an eleavtor site and of erecting at once at least a small elevator. He recommends unhesitatingly the widening of the channel to 1,400 feet with a depth in the main channel at low tide of 40 feet. He says that the harbor lines along False Creek should be sharply defined without further delay, and the channel dredged; but points out very emphatically that the dredging must not endanger the basements of the bridge piers now existing. He urges the government to secure water frontage wherever it may be had on the shores of Burrard Inlet or False Creek; and, in re-

ferring to Greater Vancouver harbor propositions, he warns promoters to make careful tests to be certain that the works will not be endangered by quicksands.

Regina, Sask.—Superintendent McKay, in his recent report on the work of the Waterworks Department of Regina during the past operating year, urges the construction of a new 27-inch main from Boggy Creek to the city in the coming year. Considerable progress has been made at Boggy Creek throughout the past year. The Tohill 5,000,000 reservoir was completed and filled. This reservoir is at such an elevation above the city that the gravity pressure is sufficient for ordinary pressure. 3,525 feet of vitrified tile pipe have been laid in the Boggy Creek basin for the collection of water, bringing the total length of collection lines up to 10,925 feet. Twenty wells have been sunk, bringing the total to date up to 35 wells, of which 33 are yielding water, the other two being plugged with sand. The duplicate Crossley engine and Allan pump installed in the pumping-house this year gives two units, either of which is able to deliver the whole city's supply. The new 5,000,000 gallon capacity pump will be nistalled at the city power house this year, but in the opinion of Superintendent McKay it will be necessary to use it only for fire purposes.

Vancouver, B.C.—Steel structural operations are reported as started on the overhead bridge to be built by the Canadian Pacific Railway from the foot of Burrard Street to the waterfront in connection with the other units of its terminal improvement scheme. Material is being assembled and work is well under way with piers, the foundations for which have been ready some time. The footings for a portion of the new structure have been already set, but until the immigration sheds are removed it will not be possible to complete the dock-end of the viaduct. However, tenders for the new immigration building have been called; and when this has been completed, the old sheds will be removed. The viaduct will be a substantial structure. The steel bents will be set in concrete piers on concrete foundations. It will be about 300 feet long and 50 feet wide, with a ramp on an easy incline to afford communication with the dock levels. Until the immigration sheds are demolished and the necessary space afforded at the north end of the bridge the viaduct will only be available for pedestrian traffic. Steps will lead from the docks to the waterfront end of the bridge.

CORRECTION.

In the article, entitled "The Rotary Type Air Pump," on page 817 of December 4th issue of *The Canadian Engineer*, the illustration, Fig. 2, showing an interesting installation of a 4,000 K.W. Surface Condensing Plant, appears inverted. We trust the reader will mark it as such without delay, so that a future reference to it will not be misleading.

PERSONAL.

W. A. CLEMENT, engineer of South Vancouver, has tendered his resignation to the Municipal Council.

PATRICK WELCH, of the firm of Foley, Welch & Stewart, prominent railway contractors on the Pacific Coast, is dangerously ill at Seattle.

E. A. JAMES, C.E., of James, Loudon and Hertzberg, consulting engineers, Toronto, has been elected to the standing of member in the American Society of Civil Engineers.

ANGUS SMITH, late City Engineer of Regina, Victoria, and North Victoria, has been chosen by the City Council of Prince Albert to succeed City Engineer M. H. Baker, resigned.

W. L. COULSON, who for several years past has been general manager of the Canadian Collieries (Dunsmuir), Limited, has resigned from that position in order to obtain the rest necessary for his health.

T. C. KEEFER, C.M.G., Ottawa, who was recently elected an honorary member of the American Society of Civil Engineers, and a few months previous, of the Institution of Civil Engineers of Great Britain, entered upon his ninety-third year a few days ago.

GEORGE WESTINGHOUSE was formally awarded the Grashof medal at the annual meeting of the American Society of Mechanical Engineers in New York last week. This is the highest honor which the engineering profession in Germany can bestow upon any individual.

HILDER DAW, A. M. Can. Soc. C.E., has been engaged by the city of Sherbrooke, Que., to revise the existing plans and to design an adequate system of sewers for the city. Mr. Daw has had some years' experience in England upon drainage and sewage purification work, and has spent seven years in America upon similar work.

The City Council of London has appointed Hon. Adam Beck and Mr. Phillip Pocock, chairman of the Water Commission, for a term of two years, and Messrs. William Spittal and M. D. Fraser, for a term of one year, as Commissioners to electrify and operate the London and Port Stanley Railway. Mayor Graham is an ex-officio member.

GORDON KRIBS, the contributor of the first article in this issue, will be remembered by many of our readers as a graduate, with the class of '05, in engineering of the University of Toronto. He was then associated with the firm of Smith, Kerry & Chace, and for several years managed a branch office of that firm at Portland, Ore. Since then he has resided in Dallas, Texas, as assistant chief engineer of the Texas Power and Light Company.

R. P. D. GRAHAM has been appointed Canadian sales manager of the Goodyear Tire and Rubber Company, succeeding P. D. Saylor. Mr. Saylor, who won an enviable reputation while at the head of Canadian sales of both tire and mechanical rubber goods, has been advanced to the presidency and managing-directorship of Goodyear Tire and Rubber Company (Great Britain), Limited, with headquarters in London, Eng. While regretting his departure from Canada, Mr. Saylor's many friends are delighted by his appointment to such an important position. He will now have charge of all Goodyear sales throughout the world with the exception of the American continent.

PHIL. H. MOORE, who was formerly engineer of the McKiernan-Terry Rock Drill Co., of New York, and who has been for some time past sales manager of the cement mill and mining machinery department of Canada Foundry Company, has resigned to become general manager of Rock and Power Machinery, Limited. The last named firm is a new concern organized by Mr. Moore and four well-known Canadians to act as sole Canadian sales agents for a number of United States manufacturers of rock drills, crushers, hoists, pumps, concrete mixers, mining machinery, etc. The head office will be in the Royal Bank Building, Toronto, with sales offices in the King Edward Hotel, Toronto, and in Montreal, Winnipeg and other cities.

E. H. BENNETT, Chicago, has been engaged by the Ottawa and Hull City Planning Commission to take charge of the replanning of these two cities. E. L. COUSINS, engineer Toronto Harbor Commission, was appointed to assist him. As announced in this journal some months ago, the Commission propose to prepare a comprehensive plan for the enlargement and beautification of these cities and surrounding territory, the plan to include park schemes, arrangement of governmental and civic buildings, and indus-

trial sites, a treatment of the waterways, etc. The preparation of these plans constitute the work of the Commission. It is being financed by the Government and the cities, the Government to pay 50 per cent. of the cost, the city of Ottawa 40 per cent. and Hull the remainder.

ADAM CAMERON, M.A., B.Sc., who succeeds Prof. C. M. Carson as head of the Department of Chemistry at the University of New Brunswick, Fredericton, N.B., Professor Carson having resigned to become Professor of Chemistry at the Michigan College of Mines, has recently assumed his official duties.

Professor Cameron was born in Perthshire, Scotland, and as a student had a distinguished career at the University of St. Andrew's, where he later held the Carnegie Research Scholarship. In conjunction with Professor J. C. Irvine, of that University, he conducted valuable research on the sugars, the results of which work were published in the Transactions of the Chemical Society. Later, as assistant to Dr. James Walker, Professor of Chemistry in the University of Edinburgh, he spent five years of active study and research. He comes to Canada direct from the University of Edinburgh, and will be a valuable asset to the Department of Chemistry in the University of New Brunswick.

Adam Cameron, M.A., B.Sc.,
Professor of Chemistry, University of New Brunswick.

T. R. DEACON President and General Manager of the Manitoba Bridge and Iron Works, was, by acclamation, re-elected mayor of the city of Winnipeg on December 2nd.

The Shoal Lake water scheme of the Greater Winnipeg Water District, as it now stands, having successfully passed the periods of contemplation and discussion and reached the stage where actual engineering work is in progress, is the result of the untiring energy which Mr. Deacon has put into it. The furtherance of the scheme is largely accountable to him and his achievements in this respect are remarkable, considering the gigantic proportions of the enterprise, and a good deal of adverse opinion which had to be overcome.

Mr. Deacon graduated from the School of Practical Science, Toronto, with the class of 1891. He followed his profession of civil engineering for eleven years, during which period he was for a time town engineer of Rat Portage (now Kenora), Ontario. In 1902, he founded the Manitoba Bridge and Iron Works at Winnipeg, and since that time has taken a very prominent part in the municipal and administrative duties as a citizen. In 1907, he became a member of a commission to investigate the water supply of the city. Three years later, he was a commissioner in connection with the Workmen's Compensation Act. For two years he was Provincial Vice-President of the Canadian Manufacturers' Association, and for four years a member of the Council of the Winnipeg Board of Trade.

The admirable combination of finance, commerce and engineering, of which it is his good fortune to have such a composite knowledge, fits him well for the position which he now holds, and his re-election by acclamation to the chief executive chair in Winnipeg civic administration, is an indication of the evidences of his efficiency and capability to handle, among other things, the great undertaking upon which Winnipeg is entering to procure a safe and sufficient water supply.

BACK COPIES WANTED.

One of our subscribers, anxious to bind his copies of *The Canadian Engineer*, is minus the following issues: Feb. 19th, 1909; Jan. 19th, 1911; Jan. 26th, 1911; Feb. 9th, 1911; March 16th, 1911; March 30th, 1911; April 6th, 1911; April 13th, 1911; April 20th, 1911; April 27th, 1911; May 4th, 1911; May 11th, 1911; May 18th, 1911; May 25th, 1911; June 1st, 1911, and would be glad to pay 25 cents per copy for any of them. Will subscribers who happen to have these numbers, and who do not care to keep them, kindly send them in to this office, and we will see to it that they are put into the hands of the party interested?

OTTAWA BRANCH, CANADIAN SOCIETY OF CIVIL ENGINEERS.

The Ottawa Branch of the Canadian Society of Civil Engineers held its annual dinner at the Chateau Laurier on December 4th, and the function was well attended. Mr. Geo. A. Mountain, president of the Branch, presided, and his associates at the head table were Prof. Adam Shortt, Collingwood Schreiber, Lieut.-Col. Anderson, G. J. Desbarats, D. McPherson, T. C. Keefer, Mr. A. St. Laurent, and G. A. Mothersill.

COMING MEETINGS.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS.—Annual Meeting to be held in New York, December 10th to 13th. Secretary, C. D. Odsen, Polytechnic Institute, Brooklyn, N.Y.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS.—Seventh Annual Convention will be held at Great Northern Hotel, Chicago, December 29th to 31st. Secretary, I. W. Dickerson, Urbana, Ill.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

Barrett Specification Roofs

Low Cost—Long Service

Metal roofs require painting every few years, most ready roofings require coating regularly, but with Barrett Specification Roofs *there is no maintenance expense.*

Barrett Specification Roofs are roofs of coal tar pitch and tarred felt, with a top surface of slag, gravel or tile, *laid according to the Barrett Specification.*

This specification is simply the standard formula for building a first-class roof of this character.

It is possible, of course, to make an inferior roof of these materials either by poor workmanship or by using insufficient and poor goods. But if the Barrett Specification *is followed absolutely and the materials called for are used*, you are certain of getting the best value in roof coverings.

Such roofs usually last twenty years and over without leaks or repairs.

Barrett Specification Roofs are almost universally used on factories and buildings of large roof areas and where costs are carefully figured. They are equally good for city dwellings, warehouses, railroad buildings, etc.

Copy of the Barrett Specification, with diagrams, mailed free on request to nearest office.

McGill Building
Montreal, P. Q.

Architect: R. E. Bostram
General Contractor
C. E. Deakin
Roofers: Campbell & Gilday

Special Note We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding. If any abbreviated form is desired, however, the following is suggested: ROOFING—Shall be a Barrett Specification Roof laid as directed in printed specification, revised August 15, 1911, using the materials specified, and subject to inspection requirement.

THE PATERSON MFG. CO., Limited

Montreal Toronto Winnipeg Vancouver St. John, N. B. Halifax, N. S. Sydney, N.S.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20907—November 25—Authorizing G.T.R. to construct extension to its siding into premises of Manley Chew, on Lot 21, Con. 3, Tp. Tay, Co. Simcoe, Ont.

20908—November 27—Authorizing C.N.R. to remove spur to Exhibition Grounds, City of Brandon, Man., constructed under Order No. 18348, dated December 20th, 1912.

20909—November 28—Extending, until Dec. 31st, 1913, time within which B.C. Electric Ry. Co. complete work at crossing of tracks of Esquimalt and Nanimo Ry. Co., near Russell, B.C., as required by Order No. 18733 dated Feb. 18th, 1913.

20910—November 27—Authorizing C.P.R. to construct spur for Pembroke Shook Mills, Limited, Pembroke, Ont., from a point on Southwesterly limit of right-of-way of C.P.R. at mileage 106.5 from Ottawa, Chalk River Sub. Div., Eastern Div., into premises of Pembroke Shook Mills, Limited, in Lot 18, Con. 1, Tp. Pembroke, Ont.

20911—November 29—Anthorizing G.T.P. Branch Lines Company to carry traffic over portion of Mountain Park Coal Branch, Alberta, between mileage 0 and 30.24; trains be limited to a speed not exceeding 12 miles an hour.

20912—November 25—Directing that special eastbound tariff rates from Vancouver, B.C., published by C.P.R. from time to time, to apply to carload shipments of lumber, shingles, and articles taking lumber and shingle rates, shall, with addition of not more than 1c. per 100 lbs., apply as joint rates from stations between Vancouver and New Westminster on line of V.V. and E. Ry. and Nav. Co., (operated by G.N.R.), to carload shipments of same articles, to same points, which are routed via Vancouver or New Westminster and C.P.R., or C.P.R. and railways connecting therewith. G.N.R. receive not less than 2½ cents per 100 lbs. to Vancouver or New Westminster as its proportion of said joint rates. C.P.R. furnish new rates from Vancouver, together with regulations and conditions pertaining thereto, to G.N.R. so that new joint rates from said stations of V.V. and E.R. and N. Co. become lawfully effective, simultaneously with new rates from Vancouver to same points. Rescinding Orders Nos. 7277 and 9187, dated 16th June, 1909, and 7th January, 1910, respectively.

20913—November 28—Amending Order No. 20411, dated September 23rd, 1913, by striking out words, "within ninety days from date of this Order," in first line of paragraph 1, operative part of said Order, and substituting therefore words, "when its railway is ready for operation."

20914—November 28—Authorizing C.P.R. to construct Lacombe-Easterly Branch of Calgary and Edmonton Railway across two (2) highways, namely,—1. West Boundary, mileage 181.93 N.W. ¼ Sec. 19-33-28, W. 3 M. 2. West Boundary, mileage 186.01, N.W. ¼ Sec. 23-33-28, W. 3 M.

20915—November 29—Authorizing C.P.R. to construct, by means of grade crossing, across highway in Lot 109, (Provincial Government Survey), East Kootenay District, B.C., at mileage 64.32.

20916—November 29—Authorizing C.P.R. to construct road diversion in Sec. 27-8-8, W. 3 M., Sask. Also construct Weyburn-Stirling Branch across highway between Secs. 27 and 28-8-8, W. 3 M., Sask.

20917—November 29—Amending Order No. 18457, December 30th, 1912, by striking out words, "J. J. Wells, Assessment Commissioner of Fort William," in lines 2 and 3, paragraph 3 of Order, and substituting therefor "Hugh O'Leary, Esquire, Senior Judge, Dist. of Thunder Bay.

20918—November 29—Approving revised location C.N.O.R. through unsurveyed territory at Clemow Lake, Tp. Barron, Dist. Nipissing, Ont., mileage 133.45 to 134.75.

20919—November 29—Authorizing C.N.O.R. to open for traffic branch line, Oshawa Station to material yard, south of William St., town of Oshawa, Ont., a distance of 2¾ miles.

20920—November 28—Authorizing C.N.R. to construct spur for Laurentia Milk Co., town of Battleford, Sask.

20921—November 29—Extending, until April 1st, 1914, time within which subway be completed at Thompson Road, Tp. Bertie, Ont.; pending completion of subway, G.T.R., at own expense, employ day and night watchmen at said crossing.

20922—November 29—Authorizing G.T.R., to operate trains over interlocking plant, St. Lambert, Que., without first being brought to a stop.

20923—November 27—Authorizing G.T.R. to construct highway between Secs. 27 and 28-35-14, W. 3 M., Sask., across main line at M. 523.6.

20924—November 28—Authorizing V.V. and E. Ry. and N. Co. to open for traffic double track between mile post 145.84 and 153.619, B.C.

20925—November 25—Adding rating of 4 the class for peanut butter in carloads, to Canadian Freight Classification, said amendment be included in proposed Supplement No. 2 to Canadian Freight Classification No. 16, submitted by Canadian Freight Association for approval by the Board.

20926—November 29—Authorizing C.N.O.R. to construct transfer tracks between Oshawa Railway Company and Oshawa spur of C.N.O.R., east side of Lot 9, Con. 11, town of Oshawa, Ontario.

20927—November 29—Amending Order No. 20647, by striking out paragraph 3 and substituting following:— 3. Applicant Company put pipes in larger pipe-casing in such way that they may be withdrawn for repairs; and reserving right to make necessary repairs to Grand Valley Railway Company.

20928—December 2—Approving and authorizing clearances as shown on plan of Montreal Ice Company, Limited's buildings at siding of Canadian Pacific Railway, village of Como, Que., subject to condition that men be kept off sides of cars while operating said sidings.

20929—December 1—Authorizing C.P.R. to open for traffic portion of deviated line at Bridge No. 39.49, North Bay Subdivision, Lake Superior Division, Ontario.

20930—December 1—Authorizing C.P.R. to open for traffic Boissevain Lauder Branch, Man., mileage 00 to 36.4.

20931—December 2—Approving plans showing automatic signals to be applied on portions of C.P.R. Company's Eastern Lines, namely:—1. Montreal Junction to Iberville Junction, Montreal Terminals Farnham Subdivision; 2. West Toronto to Islington, London Subdivision; 3. Markstay to Stinson, Cartier Subdivision; 4. Mattawa, North Bay Subdivision and 5. Renfrew to Eganville, Chalk River Subdivision.

20932—December 1—Authorizing C.P.R. to construct, subject to terms of consent of Gus Pech Foundry and Manufacturing Company, spur for city of Regina, Sask., and to alter spur for Gus Pech Foundry and Manufacturing Company, Regina, Sask.

20933—December 1—Approving locations C.P.R. stations on Virden-McAuley Branch, Man., namely:—1. Two Creeks, mileage 13.5, N.W. ¼ Sec. 19-12-26, W. 1 M., and 2, at Harmsworth, mileage 8.7, N.W. ¼ Sec. 33-11-26, W. 1 M.

20934—December 1—Authorizing Tp. Magog, Que., at its own expense, to construct highway crossing over C.P.R. at Lot No. 4b, Rge. 21, Tp. Magog, Que.

20935—November 29—Authorizing C.P.R. to construct spur for Halliday Bros., Winnipeg, Man.

20936—December 1—Extending for a period of 30 days from date of this Order, time within which G.T.R. install bell at crossing of Mill St., Milverton, Ont.

20937—December 1—Authorizing G.T.P. Ry. to construct spur for James Latimer, Edmonton, Alta.

20938—December 1—Authorizing C.N.O.R. to construct its ballast pit spur across 2 highways, Tp. Gloucester, Co. Carleton, Ont.

Tanks for Sprinkler Systems.

MANUFACTURER OF

Galvanized Wire Machine Banded

RAILWAYS—STEAM AND ELECTRIC.

Hamilton, Ont.—It is believed that Engineer Royce's recommendation to the Ontario Railway Board will be to give Mr. G. F. Webb three weeks in which to put the east end incline into operating condition, and hope is entertained that the mountain situation will be solved by New Year's Day.

London, Ont.—The city council has given its ratification of the commission to operate and construct the electrified London and Port Stanley Railway. The motion was passed appointing Messrs. Beck, Pocock, M. D. Fraser and Alderman Spittal.

London, Ont.—As a result of two resolutions passed at the last session of the Middlesex county council, the Hydro-Electric Power Commission of Ontario will be petitioned to conduct surveys, supply estimates of cost of construction and maintenance on two electric radial lines within the county. One proposed line is from London to Stratford via St. Marys; and the other, from London to Grand Bend.

+—Montreal, Que.—The Montreal and Southern Counties Railway Company has awarded the contract to the NATIONAL STEEL COMPANY of Hamilton for six new passenger coaches with the latest equipment and five feet longer than the cars now in use; also for two trailer cars and two express cars.

Ottawa, Ont.—The cost of building the new St. Lawrence and Ottawa Electric Railway was announced to be between seven and eight million dollars, and it is understood that the bonds of the company will be placed for sale on the English market before next spring. It is believed construction work on the Britannia line to the South March Rifle Ranges will be started early next summer. Work of building the Morrisburg and Ottawa branch of the road will also likely be commenced next spring. It is also understood that a private right of way will be purchased to bring the interurban cars to the city terminal.

Ottawa, Ont.—The new Canadian transcontinental railway company will be capitalized for $1,000,000,000, large financial interests being at its disposal both in New York and in London. The line is to run from Cape St. Charles in Labrador to Dean Inlet on the Pacific Coast; and all arrangements have been completed for its incorporation at the next session of Parliament.

St. Catharines, Ont.—The Grantham township council has passed a by-law allowing Messrs. Baldry, Yerburgh and Hutchinson, contractors for No. 2 section of the Welland Ship Canal, the privilege of laying a single railway track on the road allowance between the 5th and 6th concessions for a period of five years.

St. Thomas, Ont.—The outcome of the meeting of the street railway committee of the city council was the decision that no by-law asking for funds to improve the street railway roadbed will be submitted to the people at present.

St. Thomas, Ont.—Railway directors of the London and Lake Erie Transportation Company have inspected the proposed route of the extension of the company's line from Union to Sparta, and have expressed themselves as well pleased with the future prospects of the line, which is planned to run through the centre of the most important fruit-growing district in Elgin county.

GARBAGE, SEWAGE AND WATER.

+—Assiniboia, Man.—The following tenders for sewer construction in the Deer Lodge sub-division have been awarded by the council of the municipality of Assiniboia:—Mandeville Street, W. H. WARRACK, $3,937.25; Guildford Street, MOEN, SWEENEY AND HORN, $4,204.60; Sharp Boulevard, JACKSON AND SONS, $6,204.75; Conway Street, C. VANHORRENBECK, $9,969.40.

Calgary, Alta.—The city will soon be in the market for water meters. A. W. Ellson Fawkes is city waterworks engineer, from whom all information can be obtained regarding quantities, etc.

Cornwall, Ont.—A deputation from Cornwall has waited upon the Ontario Government to seek a measure of aid in respect to two drainage schemes in which the township of Cornwall is involved. The government consented to take the debentures at 4 per cent. for the Dixon Creek drain, and will consider the Stoney Creek scheme.

+—Kingston, Ont.—The utilities committee has awarded the contract to the DIETRICH CONSTRUCTION COMPANY to lay conduit main from the power house on Queen Street to Princess Street.

London, Ont.—The city council has decided to resubmit to ratepayers in January the waterworks-hydro separation by-law. The by-law calls for the council to cease its control of the waterworks and to hand back the administration of the department to the water commission.

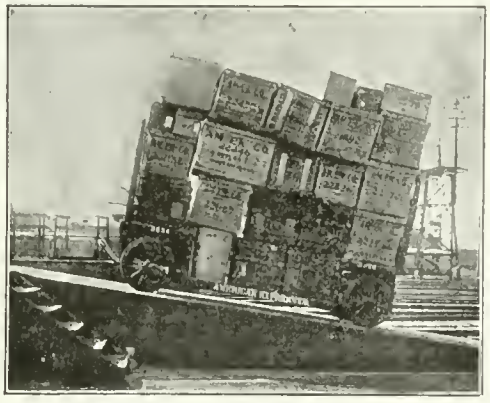
▲—Ottawa, Ont.—Tenders will be received up till February 3rd, for about 42 miles of welded steel pipe of 54-inch internal diameter, about 32 miles of welded steel pipe of 58-inch internal diameter, and about 11 miles of welded steel

A Combination in the Interest of Trade

Combinations in business are all right when they make for greater efficiency and better service to the public.

Our business is a combination of many businesses, or special lines, into a great "Departmental House for Mechanical Goods." We find by organizing our business along departmental lines that we can serve industrial Canada more efficiently, more economically and in a way that makes for the best interests of our customers.

You will find it a great convenience to deal with a House that can supply you practically anything you require in the mechanical line all "under one roof" One of the two items mentioned below may interest you



Elwell-Parker Electric Trucks

Wherever used have shown an actual saving of from 25 to 65 per cent., both for railroads and industrial concerns. One large Canadian plant trying electric trucks for the first time claims that each truck, operated by one man, has replaced eight men with eight wheelbarrows.

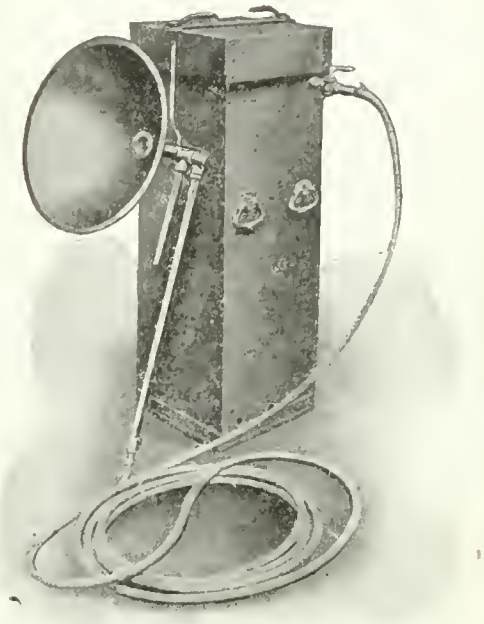
The truck shown above is one of the many types of Elwell-Parker Electric Storage Battery Trucks used by the American Express Co. The Canadian Pacific also use these trucks.

Elwell-Parker Electric Trucks are equipped with Edison Storage Batteries which are now recognized to be about the best on the market. Edison Batteries increase greatly the efficiency of the electric truck. We think so much of them that we would not advise you to purchase any electric truck that was not equipped with Edison Batteries.

Ellwell-Parker Trucks are extremely easy of operation, in no way requiring skilled labor, and by having a spare battery set can be worked continuously without injury

If you are extending or rebuilding your plant it will pay you to investigate this well known truck.

Ask for Bulletin 107.



The Milburn Light

The No. 3-W Milburn Acetylene Light shown here gives from 5,000 to 12,000 candle power and lights 1,500 feet. The light follows the crane or shovel and throws its rays directly on the work. It lights instantly, requires no attention, and positively defies wind and weather. Has water tight cover and is made to withstand hard usage, the vibration and movement of cranes, steam shovels and dredges. Supplied with 15 inch aluminum reflector and 25 feet of armoured hose with connections. Cost 4 to 6 cents per hour to operate. Over 70,000 Milburn lights have been sold.

Ask for catalogue of Milburn Lights.

pipe of 51-inch internal diameter. Plans and specifications may be from the City Engineer of Ottawa, or from Sir Alex. Binnie, Son and Deacon, St. Stephens House, Victoria Embankment, London, S.W., Eng. Signed, Sir Alex. Binnie, Son and Deacon.

Port Arthur, Ont.—After examining Port Arthur's new sewage plant and plans for extension, Mr. Fuller, of New York, the greatest authority on sewage and waterworks systems in North America, approved before a special meeting of the board of control the plans of City Engineer Jones and Mr. T. Aird Murray, of Toronto.

Port Arthur, Ont.—The by-law providing for the extension of the sewerage system in Port Arthur, and for the issuance of debentures for $53,740 to cover the cost, has been prepared for submission to citizens, and has been advertised.

▲—**Toronto, Ont.**—Tenders will be received up till December 16th, 1913, for the construction of sewers on a number of city streets. Plans and specifications may be obtained from the office of the Commissioner of Works, Toronto. Signed, H. C. Hocken (Mayor), Chairman, Board of Control.

▲—**Toronto, Ont.**—Tenders will be received up till December 15th for the construction of a sewer on Kennedy and Barrie Avenues, in the Township of York. Plans and specifications may be obtained from the office of the township engineer, Mr. Frank Barber, 57 Adelaide Street East, Toronto, Ont.

Victoria, B.C.—City Hall officials believe that the Victoria Council will reject the new tenders for rivetted steel pipe work in connection with the Sooke Lake water system, and will undertake the project by day labor.

Victoria, B.C.—Since the decision of the city council to carry out the construction of the pressure pipe from Humpback reservoir to the city by day labor the water commissioner and consulting engineer have been engaged in looking into the matter, and into the prospects of either purchasing and extending the plant started at Thetis Cove, Esquimalt harbor, by the Westholme Lumber Company, or else starting a new plant. Unless the receiver for the company will sell at a modest figure, a new undertaking will be initiated, and the work put in hand, its completion entirely depending on what financial arrangements can be made, the same financial problem applying to its prosecution by day labor as would have been experienced by contract.

LIGHT, HEAT AND POWER.

Brantford, Ont.—The Hydro Electric Commission has reported to the township clerk in reference to the supplying of power to residents of the township in the vicinity of Brantford. The commission is in communication with the city with regard to the matter of the city extending its system into the township to the districts desiring power.

Calgary, Alta.—The Eau Claire Lumber Company has decided to increase its plant, and will install two gas-driven electrical generator units, which will develop 1,500 kilowatts, and two large turbines, at a cost of $300,000. The work will not be undertaken until next spring. When the new equipment is installed, the company will be able to develop at least 2,000 h.p. in addition to that which it is at present supplying which is about 1,800 h.p.

Chatham, Ont.—At a special meeting of the city council it was practically decided to purchase the gas and electric light plants of the Chatham Gas Company at a price of $410,000, to be used as a means for introducing and distributing Hydro-Electric power in Chatham.

Edmonton, Alta.—That private corporations believe they can supply electrical energy to the city at a cheaper rate than it now costs the municipal plant to produce it, is evidenced by the fact that four companies are planning to lay proposals before the city council. Three of these concerns propose to place power plants at the mouths of coal mines. J. D. McArthur, president of the Edmonton-Dunvegan and British Columbia Railway, with D. R. Fraser and John Cameron are stated to be at the head of one of the companies. A fourth company is composed of Spokane men, who are planning to put in a hydro-electric plant on the G.T.P., just near the British Columbia border.

Fredericton, N.B.—The Eal River Light, Heat and Power Company have offered to supply electrical power for the public services in Fredericton, at the rate of 2 cents per kilowatt on a long-term contract. The proposition was made to the city council by Messrs. Andrews and Murchie, of St. Stephen, and R. G. Lee, of this city, who appeared on behalf of the company with Elecerical Engineer Prey, of Calais, Me., who had made an investigation of local conditions some time ago and estimated that about 450,000 kilowatts would be used annually in the existing services.

Hamilton, Ont.—Mr. E. I. Sifton, chief engineer of the Hydro, has submitted to the controllers an estimate of $15,490.35 for the installation, maintenance and operation of approximately 1,668 standard 100-watt tungsten lights, and approximately 273 corner 250-watt tungsten lights, in the district east of Sherman Avenue, which has been asked for by a committee of the board of works.

+ **Montreal, Que.**—The contract has been awarded the CANADIAN WESTINGHOUSE COMPANY of Hamilton, for the electrical equipment of an order of cars from the National Steel Company for the Montreal and Southern Counties Railway Company.

+—**Montreal, Que.**—The contract has been awarded the CANADIAN GENERAL ELECTRIC COMPANY by the Montreal and Southern Counties Railway Company for the electrical equipment of the Rougemont sub-power station.

Ottawa, Ont.—At the suggestion of the superintendent of water powers, the Minister of the Interior has placed under reservaion all vacant Dominion land that may be valuable for the development of water power. One of these includes Vermilion Falls on the Peace River, and there are similar reservations in the rivers of Manitoba, Saskatchewan, Alberta and British Columbia.

Ottawa, Ont.—The board of control has considered the municipal gas project for Ottawa and has decided that more definite information as to the comparative cost of gas and electricity for heating purposes must be had before a report is prepared for the city council on the municipal gas proposition.

Ottawa, Ont.—The Economical Light, Heat and Power Company, of Montreal, has written the city clerk, asking that they be allowed to install a gas plant in Ottawa. They have a process for making gas from peat, and they ask from the city permission to install plant and burrow for the pipes. They state they will be able to supply gas at 75 cents per thousand cubic feet.

Ottawa, Ont.—Tenders will be received up till January 8th for heating and ventilation of the Post Office building at Quebec P.Q. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

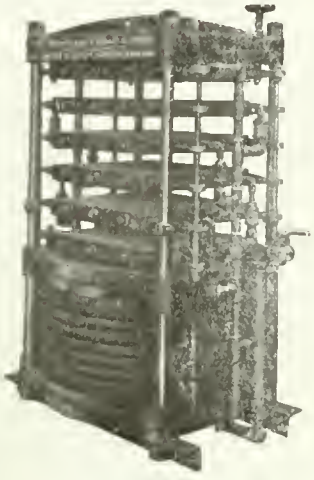
+—**Toronto, Ont.**—The contract has been signed between the HYDRO-ELECTRIC POWER COMMISSION and the Ottawa and Hull Electric Co. for the supply of 20,000 h.p., the contract to run for 33 years in periods of 13, 10, and 10 years, terminable by the commission at any time on two years' notice. The new price is $14 per h.p., with a graduated reduction to $11 on the following scale:—Up to 5,000 h.p., $14; 8,000 h.p., $13.50; 10,000 h.p., $13; 12,000 h.p., $12.50; 14,000 h.p., $12; 16,000 h.p., $11.50; 18,000 h.p., $11.

Vancouver, B.C.—A report submitted to-day by the chief engineer of the British Columbia Electric Railway Company showed that the company has at the present moment no less than 50,000,000,000 gallons of water in their dam at Lake Coquitlam for power purposes. This will be used to a large extent for the supply of light and power on the north shore of Burrard Inlet.

Walkerville, Ont.—The ratepayers have recently approved of two by-laws relative to the adoption of Hydro-Electric power—eg., the Enabling Act, authorizing Walkerville to enter into a contract with the Hydro Commission; and the by-law authorizing the issuance of debentures to cover the cost of a distributing station. Walkerville expects to contract for 1,500 h.p.

Weston, Ont.—The Weston Water, Power and Light Commission will make a bid for the contracts and extensions for Hydro power to Bolton, Woodbridge and Thistletown. Weston is the nearest distributing sub-station, and has about 13 miles of line from Cooksville. The town will communicate with the Hydro Commission to ascertain if a proposition allowing Weston to handle the needs of the three villages would be favored, and also to see if assistance in financing would be granted.

Cut Your Press Expense in Two!



75-ton Press for Vulcanizing.

Here is a Press whose initial cost is less than half that of a Ram Press plant of equal capacity—whose running expense is negligible whose upkeep cost is nil. This is because it is the simplest possible application of hydraulic pressure the

Pistonless
Hydraulic Press

Heavy, expensive foundations, motive power, pump, piston, packings, leakage, expert attention—all are eliminated. The water from any tap, under ordinary service pressure, multiplies this pressure in an armoured collapsible cylinder, the head of which forms the platen of the Press. Nothing could be simpler or more effective.

The Pistonless Press is made in sizes and types suitable for Baling, Extracting, Vulcanizing, Printing, Bookbinding, Electrotyping or any other application of heavy pressure. Write for full information, stating the purpose for which you require a press, to

MONTREAL TORONTO VANCOUVER

BRIDGES, ROADS AND PAVEMENTS.

Assiniboia, Man.—The council of Assiniboia has just awarded a heavy paving contract to the BITULITHIC COMPANY, which constructed the Winnipeg-St. Charles Road. The result will be the extension of the present asphalting on Portage Avenue from St. Charles, its present ending, to Headingly, making a continuous road from Winnipeg to Headingly, ultimately to become part of the proposed transcontinental highway. The contract, which is for 90,000 square yards at a cost of $250,000, provides for a width for the first mile and a half past St. Charles of 24 feet, the remaining distance, 5½ miles, to be 18 feet wide.

London, Ont.—It is expected to submit to electors in January a by-law providing for money necessary for the improvement of the proposed east-end market. Chairman G. E. Rose of the market committee and City Engineer Ashplant are reporting on the cost of improvements. A brick, gravel, or concrete bottom will be constructed; also buildings and sidewalks. The city engineer will also report on the cost of paving the uptown market.

London, Ont.—The continuous road idea as proposed by the Dominion Highways Commission has met with the disapproval of the city council, and a committee is preparing a resolution to be presented at the meeting of the commission to be held in London on December 16, after having been approved by council.

Macleod, Alta.—The urgency of requesting the management of the C.N.R. to build two subways in Macleod before the construction work on the new line is started, has been set forth by Mr. J. L. Fawcett, vice-president of the city Board of Trade. Consultation upon the matter will be held with the city council.

+—Ottawa, Ont.—The DICKSON BRIDGE COMPANY has been awarded the contract for Campbellford Bridge at Lock 20, Galops Canal, at the recent session of Cabinet Council.

+—Ottawa, Ont.—The Dominion Government has awarded the contract to McKINNON, HOLMES AND COMPANY for bridges at Black River, Rivière le Bras, Sayabac, Ivory Road and Oxford Subway.

+—Ottawa, Ont.—The contract has been awarded by the Cabinet Council to the CANADIAN ALLIS-CHALMERS COMPANY for the construction of three bridges—at West River, at Barney's River, and at French River, N.S.

+—Ottawa, Ont.—The contract has been awarded by the Cabinet Council to the DOMINION BRIDGE COMPANY for four bridges—over the Becancour River, over the N.T.R. bridge, over the Rivière du Loup and over the Rivière du Sud.

Ottawa, Ont.—City Engineer Currie has written the board of control, stating that the bridge over the Rideau River at Billings' Bridge was in an absolutely dangerous condition, and that he would no longer assume responsibility. He asked that the bridge be closed at once. Concerning the suggestion of repairing the present bridge for use until the new one was constructed, he said that this would cost $8,200, which would be more than the cost of a temporary bridge; and moreover, that the abutments for the new bridge would have to be placed where the piers of the present structure are. Mr. Currie's letter is to be forwarded to the city council with the hope that that body may agree to pay part of the cost of the temporary bridge.

Peterboro, Ont.—The Government has shown its endorsation of the C.P.R.'s proposal to construct a 37-foot swing span in connection with that company's new bridge. The company will, in all probability, proceed with the eastern and western sections of the bridge. The centre span, which will constitute the swing portion of the structure, will not be erected for some months, as it will be necessary to make some extensive alterations to the original plans.

Peterboro, Ont.—Over 800 citizens have signed their names to a petition recently presented to the city council asking for a new bridge across the Otonabee River from the end of Dalhousie Street to Maria Street.

Thorold, Ont.—The municipal council recently decided that Mayor Broderick and Mr. McMann should wait upon Mr. Weller to request the building of a bridge from the G.T.R. station to Regent Street, the present road being both inconvenient and dangerous.

▲—Toronto, Ont.—Tenders will be received up till December 17th, 1913, for furnishing labor and material for waterproofing eight subways at North Toronto. Plans and specifications may be obtained from the office of the Engineer of Grade Separation, 262 Avenue Road, Toronto. B. Ripley, Esq., Engineer of Grade Separation.

Toronto, Ont.—At the last meeting of the city board of control, it was decided to provide labor for the unemployed by spending $250,000 by day labor on the grading of Bathurst and Christie Street hills. Commissioner Harris was instructed to hasten the calls for tenders, and a special meeting of council will deal with the tenders received.

Toronto, Ont.—The board of control has decided to provide the $3,000 required to change the plans of the new bridge of the C.P.R. over the Don ravine east of Leaside. The new bridge is close to the present one and the piers joggle, shutting off a roadway for the projected boulevard belt. Piers are to be changed to provide for the roadway.

Vancouver, B.C.—Tenders will be called on recommendation of the city engineer and board of works for new pavements, the estimated cost of which is over $500,000. Bids will be asked for immediately and will be considered by the committee on December 23.

INDUSTRIAL WORKS.

Fraser River, B.C.—Tenders will, it is expected, be invited within the next six weeks for the second "unit" of the Fraser River jetty; estimated cost, $750,000. Broley and Martin, contractors, will complete the first "unit" in about five or six weeks.

Goderich, Ont.—The county council of Huron has decided to urge upon the Government the completion of improvements to the Goderich Harbor as rapidly as possible. A petition will be forwarded to the Government, and it is probable that a deputation also will be sent to Ottawa.

+—Montreal, Que.—The C.P.R. have let the contract for the driving of ten miles of tunnel in British Columbia to the firm of JAMES A. McILWEE AND SONS of Denver, Colo. The contract price is $8,000,000. Work is to start on January 1, and must be completed within three years. A double-track bore five miles long will be driven under Rogers' Pass, 224 miles west of Calgary. A smaller and parallel tunnel will be driven with cross-cuts to the main survey at every 500 feet, and stations will be established from which headings will be run in either direction. In this manner the tunnel proper will shortly be driven from a dozen different directions. The contract is said to be the largest tunnel construction ever let in America. Construction camps costing $50,000 are now being erected at either portal.

▲—Ottawa, Ont.—Tenders will be received up till December 29th for the construction of a dam across the South Channel of the French River, at the head of Big Chaudiere Falls. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

+—Ottawa, Ont.—At the recent session of the Cabinet Council, the contract for dams and deepening of the channel of the Severn Bridge at Washago, Ont., was awarded to J. RODDICK at a cost of $8,925.

+—Ottawa, Ont.—The Cabinet Council has awarded to the KENNEDY CONSTRUCTION COMPANY the contract for improvements to Lock 20, Cornwall Canal, at $15,491.

Ottawa, Ont.—Tenders will be received up till January 5th for the construction of a wharf at Beloeil Village, Vercheres County, P.Q. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

+—Ottawa, Ont.—The contract has been let to the PACIFIC DREDGING COMPANY for the construction of the turning basin in connection with the Dominion Government's scheme of harbor development at False Creek, the contract price being $100,000.

+—Ottawa, Ont.—The contract for the jetty at La Prairie in connection with the King Edward Highway has been awarded to DURANCEAU & POPOURE, of Montreal, the contract price being $72,678.

Ottawa, Ont.—Tenders will be received up till December 23rd, 1913, for dredging required at Charlottetown, P.E.I. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. Signed R. C. Desrochers, Secretary.

Part II.—STATICALLY INDETERMINATE STRUCTURES AND SECONDARY STRESSES. 8vo, xvi+538 pages, 313 figures. Cloth, $4.00 net.

Part III.—DESIGN. (In preparation.)

Renouf Publishing Co.,
25 McGill College Ave.,
MONTREAL.

Vancouver, B.C.—Plans for the sea wall across False Creek at Main Street have been approved by the bridges and railways committee, and objected to by Messrs. Champion and White. The matter has been referred to a committee comprised of the chairman, the engineer and the solicitor of the Harbor Commission, for solution. The plans show two slips 150 feet deep besides the city market and Armstrong and Morrison's wharf.

Vancouver, B.C.—An immense deep-water dock scheme is being planned for the south side of False Creek. The cost of the project will run to $250,000 or more. Sites have been secured already for wharves, and supporting the scheme at present is ex-Alderman J. D. McNeill, with a number of capitalists. Mr. McNeill will investigate the latest dockage developments before the scheme for False Creek is actually begun. The proposals as now on foot provide for extensive wharfage in connection with the Dominion Government development of the deep channel, and until the greater shipping expected from the Panama Canal direction begins, the company will run a building supply and coal business as part of the project, using the wharfage to be constructed shortly.

Vancouver, B.C.—At a meeting of the West Vancouver Ferry Company, the subject of strengthening the new wharf at Hollyburn was discussed. The firm of Cartwright, Matheson and Company will be asked to make an estimate of the cost of extending the anchorage space further into the land and of strengthening the structure to withstand the high winter tides. A large amount of dredging will be required.

Vancouver, B.C.—The city council has recommended the construction of sewers on several of the city's streets, and special work in Hastings townsite, alone costing $9,500, as relief work in clearing and rough grading certain streets.

West Vancouver, B.C.—A demand is being raised among the ratepayers of West Vancouver for a new wharf to replace the rough pile wharf now existent.

West Vancouver, B.C.—Plans for a wharf at Dundarave have been approved by Messrs. McAlpine, Robertson & Company, engineers, to whom they were submitted by a deputation consisting of the reeve and councillors of West Vancouver. Tenders for construction will be called for in the near future.

Winnipeg, Man.—A by-law is advertised in Winnipeg to be submitted to ratepayers to create a debt of $85,000 for the purpose of paying the cost of construction of a garbage incinerator plant within the district of Elmwood, Winnipeg.

MISCELLANEOUS.

Brandon, Man.—Dr. Pickard, health officer for Brandon, has submitted a report to the city council on his inspection of incinerators at Moose Jaw and Regina, advocating the erection of a garbage disposal plant at Brandon. He stated that he had an offer from the Decarrie Company to erect a plant here that could dispose of 50 tons of refuse per day, and they guaranteed the cost would not exceed 60 cents a ton. The plant would cost $45,000, and it was estimated that from it 100 horse-power would be developed. Another firm of makers, Heenan & Froude, would erect a plant for $51,400, but they did not attach any guarantee as to the cost of disposal. The council referred the matter to the health committee for thorough investigation and report.

Brantford, Ont.—The United Rubber Manufacturing and Reclaiming Company has purchased a site in Brantford, and the company's general manager, R. G. Wooten, has announced that a building of concrete will be erected early in the spring.

Edmonton, Alta.—In a recent meeting called for the purpose of hearing municipal candidates, Mayor Short, in discussing next year's program of works, referred to the incinerator. He said that a movement is on foot to have a central incinerator, the one situated on the south side being too far away for any great service. The power generated from a central incinerator could be used to operate the street railway department. It is estimated that the plan would save the city about $36,000, and it will be given the serious consideration of council.

Edmonton, Alta.—A check for $300,000 has been paid over to the Alberta Farmers' Co-operative Elevator Company, Limited, representing the Government's loan of 85 per cent. of the cost of 50 elevators now in operation. The remaining $50,000 will be paid the beginning of next year.

Ottawa, Ont.—The contract has been awarded by the Dominion Government to JOSEPH SHANK for the rebuilding of the Council House, Sarnia Indian Reserve, at a contract price of $4,153.

Ottawa, Ont.—Contracts for two boats for Hudson Bay traffic are being let in Britain. These boats are being built by the North Railway Company and will ply between Fort Nelson and Port Nottawa, Quebec. They will be known as the Nottawa and the Nelson, and each will have a carrying capacity of 200,000 bushels of wheat. They will be ready for service in 1915, when the Hudson Bay Railway will be completed.

Vancouver, B.C.—Plans and specifications dealing with the partial reconstruction of the Canadian Pacific steamer Princess Mary have been discussed in a conference between Captain J. W. Troup and the heads of the British Columbia Marine Railway Company. It is understood that the contract for the lengthening of the coasting steamer will be taken in hand without delay.

CURRENT NEWS.

Bellingham, B.C.—Skagit county farmers living near the Skagit-Bellingham interurban will have their homes served with electricity by the Puget Sound Traction, Light and Power Company, and work has started stringing wires for that purpose. The company will extend the service to the Skagit and La Conner flats as fast as business will justify.

Calgary, Alta.—Four new oil rigs are at present being located in the southern Alberta oil fields, and construction work has been started on four derricks, each of which is being built by a different company.

Calgary, Alta.—Mr. Eugene Coste, president of the Natural Gas Company, has stated to the city board of trade that, with the present installed equipment, the company can furnish 15,000,000 cubic feet of gas to manufacturers every 24 hours, which would generate in gas engines 60,000 h.p. at a cost to the manufacturers of from $18 to $18.50 per h.p. President Campbell of the board of trade has given figures to prove that 68,000 h.p. a day can be supplied by the present plants in the city.

Edmonton, Alta.—Two parties of surveyors are in the field on the route of the Alberta and Great Waterways railway and construction will shortly be commenced at a point some twelve miles north of the city, where the line to Fort McMurray will branch off from the main line of the Edmonton Dunvegan railway. The yards of the latter company at Edmonton will be used as the terminals for both lines.

Edmonton, Alta.—Steel is now being laid to within ten miles of Mirror Landing on the Edmonton Dunvegan line and representations will be made to the railway commission to allow a slow train to operate on the line for passengers and freight about the first of the year.

Edmonton, Alta.—The contractors are covering with tar paper and sand the deck of the bridge over the Canadian Pacific Railway at 109th Street at the south approach to the high level bridge. The back filling has yet to be done and it is possible that the filling and paving of approaches and the laying of the block pavement on the deck of the bridge will not be done till spring.

Esquimalt, B.C.—The G. T. P. steamer "Prince John" is at Esquimalt having an oil fuel system installed, and being fitted with a manganese bronze propeller. It is understood that the contract, which is being carried out by the B.C. Marine Railways Co., will be put through with all possible speed in order that the vessel may be delivered back to her owners by the early spring in readiness for the early rush to Northern British Columbia.

Port Arthur, Ont.—Work is being rushed on the new freight steamer at the Western Drydocks in Port Arthur. The big 625 foot hulk is commencing to assume shape. The steel frame work is completed with the exception of part of the stern and the plates are now being rivetted together. It is expected that the big shoe will be placed at the stern in a few days when everything will then be in shape for the rushing of the work to completion. It is expected to launch the new steamer towards the latter end of March.

MEXICAN EAGLE ASPHALT

TRADE MARK

Delivered to meet the specifications of the American Society for Municipal Improvements, the Association for Standardizing Paving Specifications or any other standard specifications

Purchase MEXICAN EAGLE ASPHALT because:

1—It is more cementitious than other asphalts.

2 Water will not readily injure it.

3—Exposure to sun and air will not cause its deterioration.

4—It has great cohesive strength.

5—It is more ductile and flexible than other asphalts.

6—Shocks will not crack it. It is very malleable.

7—We will supply asphalt having the proper penetration for your needs.

8—It is best adapted to Canada's climate—will not mark in hot weather—nor are snow or ice likely to crack it.

9—It has over 99 per cent. bitumen. Purest on the market—therefore free from deleterious matter.

10—It is so constituted that it will not be injured by the heat necessarily applied to melt it for paving operations.

Samples, prices, analyses, etc., on request.

THE ASPHALT AND SUPPLY CO. LIMITED

TRANSPORTATION BUILDING — MONTREAL

TENDERS CALLED FOR

NOTICE TO CONTRACTORS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, up to noon, on Tuesday, December 16th, 1913, for the construction of the following works:—

SEWERS.—

Annette Street, from Quebec Avenue to Runnymede Road. Blackburn Avenue, from Gerrard Street to Mount Stephen Street. Clifford Street, from Walnut Street to Niagara Street. Danforth Avenue from Hillingdon Avenue to Woodbine Avenue. Gerrard Street and Hiawatha Road to Gerrard Street and Eight Avenue, via Gerrard Street, Coxwell Avenue and Gerrard Street. Lane 1st West of Grove, Foxley Street to 232 feet North Moore Park Drainage System, Western Section Outlet No. 1, from Rosehill Avenue and Grace Terrace to Summerhill Avenue, and MacLennan Avenue via Grace Terrace, Rosehill Avenue, Clifton Road, Oakwood Drive, Sighthill Avenue and Summerhill Avenue. Moore Park Drainage System, Western Section, Outlet No. 2, Grace Terrace from Rosehill Avenue to Clarence Street. Norway Place, Woodbine Avenue to 620 feet East. Orchard Park Boulevard, Orchard Park Road to East End. Oriole Parkway, Oriole Road to 122 feet North of Gormley Avenue. Waverley Road, North Limit lot 48, plan M. 252, to S.S Kingston Road. Warram Place, Belsize Drive to 100 feet South of Belsize Drive North. Woodbine Avenue, Kingston Road to N. C. Limits.

Envelopes containing tenders must be plainly marked on the outside as to contents.

Specifications may be seen, and forms of tenders obtained at the office of the Commissioner of Works, Toronto.

Tenderers shall submit with their tender, the names of two sureties, (approved by the City Treasurer, not members of the City Council, or officers of the Corporation of the city of Toronto), or in lieu of said sureties, the bond of a Guarantee Company, approved of as aforesaid.

The usual conditions relating to tendering as prescribed by the City By-Law must be strictly complied with.

The lowest or any tender, not necessarily accepted.

H. C. HOCKEN, (MAYOR),
Chairman, Board of Control.

Toronto, December 3rd, 1913.

CANADIAN PACIFIC RAILWAY COMPANY.

NORTH TORONTO GRADE SEPARATION.

NOTICE TO CONTRACTORS.

Sealed proposals will be received by the undersigned up to 12 o'clock noon, on Saturday, December 27th, for furnishing labor and material in connection with the waterproofing of eight subways at North Toronto.

Plans and specifications may be seen at the office of the Engineer of Grade Separation at No. 262, Avenue Road, Toronto, where proposal forms may also be obtained.

The lowest or any tender not necessarily accepted.

R. RIPLEY,
Engineer of Grade Separation.

Toronto, December 4th, 1913.

Sealed tenders addressed to the undersigned, and endorsed, "Tender for Dam on French River, South Channel, Ont.," will be received at this office until 4.00 p.m., on Monday, December 29, 1913, for the construction of a Dam across the South Channel of the French River, at head of Big Chaudiere Falls.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the offices of the District Engineers, Confederation Life Building, Toronto, Ontario; Post Office Building, Montreal, and on application to the Postmaster of North Bay, Ont.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, December 5, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—51842.

TENDERS FOR A COMPLETE MECHANICAL FILTRATION PLANT.

BOILERS, STEAM TURBO-GENERATOR PLANT AND ALL APPURTENANCES.

Tenders will be received by registered post only addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on

Tuesday, January 20th, 1914,

for the installation of a complete Mechanical Filtration Plant, Boilers, Steam Turbo-generator Plant and all appurtenances at Toronto Island.

Specifications and Tender forms may be obtained upon application at the office of Mr. James Milne, Mechanical and Electrical Engineer, Department of Works, City Hall, Toronto.

Envelopes containing tenders must be plainly marked on the outside as to contents.

The usual conditions relating to tendering as prescribed by City by-law must be strictly complied with, or the tenders may be declared informal.

Tenderers shall submit with their tenders the names of two personal sureties approved by the City Treasurer, or, in lieu thereof, the bond of a guarantee company approved as aforesaid.

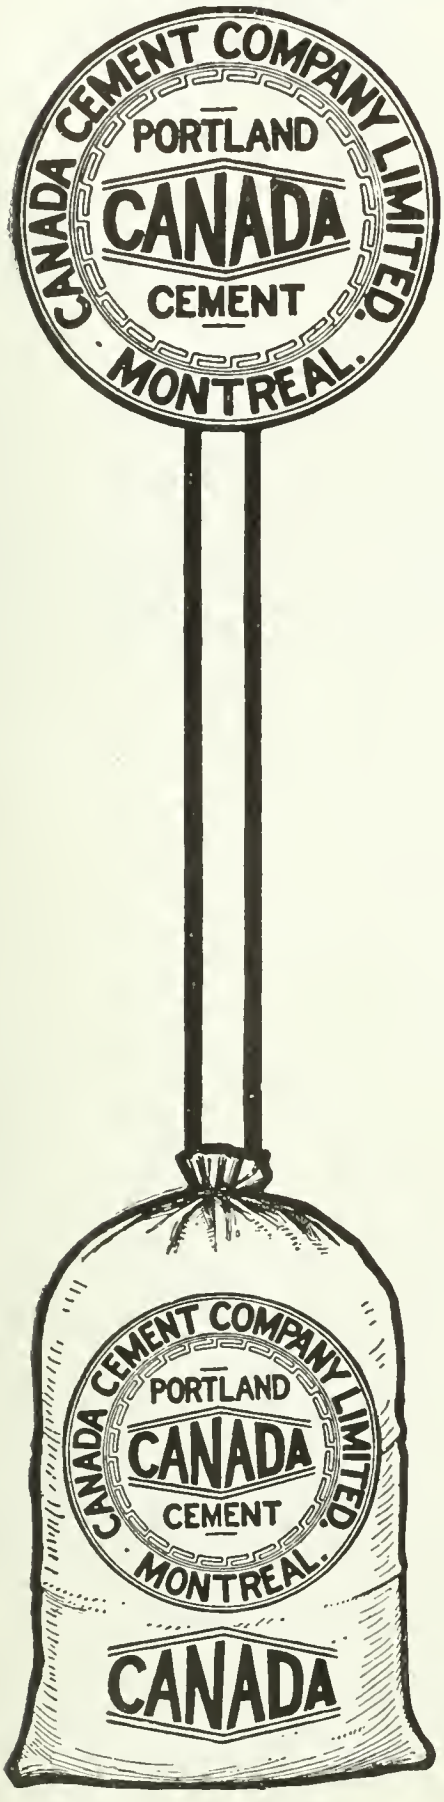
The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

City Hall, Toronto, November 25th, 1913.

(For further Tenders see Page 88.)

PERMANENCE—



an ideal that is now attainable

THE superiority of concrete over all other materials for the building of permanent structures is now generally admitted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

TENDERS FOR STEEL PIPES.

Sealed tenders in duplicate addressed one copy to the City Clerk, City of Ottawa, Canada, and the other to Sir Alex. Binnie, Son and Deacon, St. Stephens House, Westminster, London, England, and endorsed, "Tenders for steel pipes," will be received until 4 p.m. on Tuesday, the 3rd day of February, 1914, for about forty-two miles of welded steel pipe, fifty-four inches internal diameter, about thirty-two miles of welded steel pipe, fifty-eight inches internal diameter, and about eleven miles of welded steel pipe, fifty-one inches internal diameter.

Forms of tender and specification may be obtained from Sir Alex. Binnie, Son and Deacon, St. Stephens House, Victoria Embankment, London, S.W., or from the City Engineer of Ottawa, Canada, on and after the fifteenth, on receipt by them of a cheque to the value of five hundred dollars, made out to the City Treasurer of the City of Ottawa, Canada, which sum will be returned on receipt of a bona fide tender.

The lowest or any tender is not necessarily accepted.

No tenders will be considered except from actual manufacturers capable of supplying the whole of the pipes within a period of two and a half years from the date of acceptance of the tender.

SIR ALEX. BINNIE, SON & DEACON,
Engineers in Chief,
St. Stephens House,
Westminster, London.

Dated December 4th, 1914.

TENDERS FOR SEWERS

Sealed tenders, plainly marked as to contents, will be received at the office of the undersigned up to noon of **Monday, December 15th, 1913,** for the construction of a sewer on Kennedy and Barrie Avenues, in the Township of York.

Plans, specifications and all necessary information may be seen at the office of the undersigned. Lowest or any tender not necessarily accepted.

FRANK BARBER,
Township Engineer,
57 Adelaide Street East, Toronto.

Toronto, December 8th, 1913.

TENDERS FOR ANNUAL SUPPLIES.

DEPARTMENT OF WORKS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on Tuesday, December 16th, 1913.

1. Asphalt (refined).
2. Paving Blocks (vitrified).
3. Granite or Stone Setts.
4. Treated Wood Blocks.
5. House Numbers.
6. Iron and Steel.
7. Special Castings.

Specifications and tender form for any of the foregoing may be obtained upon application at the Accounting and Purchasing Section of the Department of Works, Room 12, City Hall, Toronto. Envelopes containing tenders must be plainly marked on the outside as to contents. Conditions relating to tendering, as prescribed by city by-law, must be strictly complied with, or the tenders may be declared informal. Tenderers shall submit with their tenders the names of two personal sureties, approved by the City Treasurer, or in lieu thereof the bond of a guarantee company approved as aforesaid.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

City Hall, Toronto, December 1st, 1913.

(For further Tenders see Page 86.)

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W.:—A London merchant who has taken out a Canadian patent for a compensated rapid luffing-crane with self-balanced jib, is desirous of getting into touch with a firm of engineers in the Dominion open to undertake the manufacture of the machine in Canada.

From the branch for City trade inquiries, 73 Basinghall Street, London, E.C.:—A Yorkshire manufacturing company are in the market for amber mica and would be glad to receive samples and quotations from Canadian producers. An important London firm of mineral brokers are looking for further supplies of molybdenum, chrome ore, wolfram and tin ores, and are open to consider offers of regular shipments of these ores from Canadian producers. A firm at Hamburg, Germany, who handle mica, invite offers and quotations from Canadian shippers. A Canadian company producing amber mica upon a large scale is about to embark in export trade and wishes to be placed in communication with United Kingdom importers. A firm in Montreal, which has branches in Western Canada, would like to arrange for the importation of considerable quantities of Portland cement. A company at Vancouver wish to arrange to obtain supplies of wire-drawn tungsten electric lamps, and would be pleased to receive quotations from United Kingdom manufacturers of the same. A manufacturers' agent at Montreal who specializes in machinery lines, seeks a first-class agency in gas engines.

The following inquiries relating to Canadian trade have been received:—2093.—A South African merchant is making inquiry for catalogues and prices on Canadian-made shovels. 2094.—A South African merchant asks for catalogues and prices on axes of Canadian make. 2100.—Samples and prices are asked for by a South African merchant. 2118.—An East London firm asks for prices on all kinds of Canadian lumber. 2127.—Samples and prices are being asked for by an East London importer. 2130.—A South African importer asks for prices on all kinds of Canadian lumber. 2131.—A South African firm of merchants and engineers asks for quotations on Canadian formaldehyde. 2169.—Inquiry is made by a Paris firm of brokers for the names of shippers in Canada of iron ore.

The names of the firms making these inquiries, with their addresses, can be obtained upon application to:—"The Inquiries Branch, the Department of Trade and Commerce, Ottawa," or the Secretary of the Canadian Manufacturers' Association, Toronto, or the Secretary of the Board of Trade at London, Toronto, Brandon, Halifax, Montreal, St. John, Sherbrooke, Vancouver, Victoria, Winnipeg, Calgary and Chambre de Commerce du District du Montreal.

AMERICAN ROAD CONGRESS, 1914.

The Joint Committee representing the American Highway Association and the American Automobile Association, has selected Atlanta, Georgia, as the meeting place of the 4th American Road Congress during the week of October 19th, 1914.

Sold in Canada by

AZTEC OIL & ASPHALT REFINING CO. of Canada

311 Shaughnessy Bldg., Montreal

Refined by

THE U.S ASPHALT REFINING CO.

AZTEC ASPHALT

Canadian municipal and highway engineers and road contractors should buy Aztec Asphalt on account of the qualities possessed by its bitumen. It is not—like other asphalts—merely "over 99 percent bitumen." Aztec is over 99 percent bitumen of special qualities that make it particularly suitable for Canadian requirements.

AZTEC BITUMEN

is solid, high-grade and best suited to Canadian conditions, because neither frost nor hot weather injures it. Aztec retains its tenacity under all conditions, also resisting all water action.

The extremes of temperature in most Canadian cities make asphalt more of a "problem" for Canadian engineers than it is for engineers in any other part of the Continent. Other asphalts that are entirely successful in South America, Mexico, Europe or in central or southern parts of the United States, might fail in Canada because of the extremes in temperature here.

For Canada asphalt must not only be pure (nearly 100 per cent bitumen) but the bitumen *must retain its tenacity at all temperatures*. In this regard Aztec excels. It is impervious to water, stays malleable even when buried under snow or ice for long periods, does not soften noticeably in summer and has great coherence, resisting wave tendencies.

Aztec is refined near Baltimore, Md., from liquid asphalt, or maltha, imported from Vera Cruz (Mexico), the land of the Aztecs. It is the expert North American labor, added to the high character of the Mexican maltha, that accounts for Aztec's superior qualities.

We would be pleased, upon request, to quote, send samples or mail further literature regarding Aztec Asphalt.

MONTREAL MARKET LETTER.

Montreal, Dec. 6th.

Conditions show very little change this week as compared with a week ago. In the matter of prices there is no change whatever. Until navigation opens up again all the stock will be quoted and delivered from storehouse, so that the cost of cartage and handling from the storehouse will require to be added to the previous cost on dock. As is usual in the month of December, trade is very quiet; in fact, it is rather quieter than is usually the case. There is always a rush before the close of navigation, and anyone wanting iron in the near future will place his orders before that time; others will delay ordering until after the turn of the year.

Merchant furnaces in Ontario are said to be fairly busy, but purchases are only being made for immediate requirements, there being considerable doubt on all sides respecting the near future. Reports of a discouraging nature continue to come in from across the border, and everyone seems to be a bear on the price of iron. Furnaces are being blown out, and some of the steel mills are also ceasing to manufacture. Notwithstanding this, the output is larger than the requirements, so that the orders on hand are being gradually reduced. How long this will continue is difficult to say, but in the meantime it is exercising a depressing influence not only on iron and steel and other trades of the United States, but upon the iron and steel trade of Canada. The output for the Nova Scotia Steel and Coal Company for the month of November, although smaller than that of the month of October, showed an increase as compared with a year ago. It is understood that the Dominion Steel Corporation is also showing an increased output. Prices are said to be a little disappointing, and it was not difficult to believe that this would be the case. However, both companies are said to be making a satisfactory showing. The probabilities are that the directors of each concern will meet here during the next week to decide upon the dividends. There has been no talk of any alteration with respect to the dividend of the Nova Scotia Steel and Coal Company; but, as may be remembered, there was considerable discussion a few weeks ago concerning the dividend on the common stock of the Dominion Steel Corporation, and the claim was made that this might have to be passed. The feeling here, however, is that no matter what the future may bring forth, the dividend will be declared at the usual rate during the coming week.

The various car companies are evidently not very cheerful over the outlook for orders for the coming season. These have not been given out at all freely, although the Grand Trunk is now inquiring for prices on a considerable number of cars, the number spoken of being well on towards 1,000. It is thought now that orders may be delayed until after the turn of the year.

CURRENT NEWS.

Fort William, Ont.—Although the joint street railway board will not hand over the management of the inter-city street railway until the expiration of that body's present term of office, January 1, the railway, on December 1, became two distinct systems, Fort William formally taking over its half of the line which was purchased five years ago and since managed by a joint board. Under the agreement the cities were not to assume individual management until December 1, 1913. Cars and crew run through as formerly but conductors exchange ticket boxes at the boundary between the cities.

Fort William, Ont.—Among the eleven by-laws to be submitted to the people of Fort William on civic election day, are several of engineering import; one calling for $125,000 for telephone purposes; one for $37,000 for waterworks purposes; for electric lighting purposes, $115,500; and for street railway purposes, $238,000.

Ottawa, Ont.—The Commission on Conservation is preparing a report upon the extensive timber cutting and general forest depletion in the Trent watershed, and upon the danger of this eventually removing the source of water supply and rendering useless the Trent Valley Canal. The commission will recommend that either the Dominion or Provincial government acquire properties in the district and protect the forest growth.

BRITISH COLUMBIA—Pacific Lock Joint Pipe Co., 1005 A St., Tacoma, Wash.; Globe Bldg., Seattle, Wash.

MARKET CONDITIONS

Montreal, December 8th, 1913.

Bar Iron and Steel—Trade is reported active. Bar iron, $2.05 per 100 pounds; best refined horseshoe, $2.30; forged iron $2.20; mild steel, $2.15; sleigh shoe steel, $2.15 for 1 x ⅜ base; tire steel, $2.25 for 1 x ⅜ base; toe caulk steel $3; machine steel, iron finish, $2.25.

Cement—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1 40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in. $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3 45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1-in., $3.05.

Explosives and Accessories—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25 lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4.30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $21.75 per ton; selected Summerlee, $21.25; soft Summerlee, $20.75 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19 to $19.50 per ton, on track.

Lath—See Lumber, etc.

Lumber, etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph poles: seven-inch top, cedar poles, 25-ft. poles, $2, each; 30 ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce 4-ft. x 1½ in., mill run, $3 to $3.25; pine 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2 10; XX, $2.40· XXX, $2.80.

Pipe—Cast Iron—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe—Wrought and Galvanized—Demand is fair and the market steady: —¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent off for black, and 59 per cent. off for galvanized. The discount on the follnwing is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22 50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57 50, and 3-inch $75,50; 72½ per cent. off for black, and 62½ per cent. off for galvanized; 3½-inch $95 4-inch, $1.08.

Toronto, December 10th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes—Orders continue active. Lap-welded, steel, 1¼-inch, 10c. 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $14 to $15 per M., three grades.

Broken Stone—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto 60 cents.

Cement—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks, 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot—The market is lower at 15½ to 16c., sheet cooper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps—75c. and $1 per 100; case lots, 5,000, 20 per cent. off.

Dynamite—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents per pound, 1 to 9-case lots, 50 lbs. to case. For each additinnal 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case ots and over deduct 1 cent. For 40-case lots and over deduct 1½ cents.

Fuses—Electric Blasting—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain—¼-inch, $5.75; 5-16-inch, $5.15; ¾-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3 55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40 60; 6-inch, $52.64. Galvanized Pipe, ¼-inch, $2.86; ⅜-inch, $2.86; ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead—Firmer, $5.25 to $5.50.

Pig Iron—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green $8, with a prospect of advance. Dealers are fairly busy.

Sand—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot.....	$0 25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long ...	1.00	1.60	2.60	4.00	13.00
Double junctions.....	1.25	2.00	3.25	5.00	16.25
Increasers and reducers.....	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes 9 inches and under, or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels—Active—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2 75 to $3 per 100 lbs. Extra for smaller sizes of angles and tees.

Sheet Copper—22c. per lb.

Sheet Steel—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 28-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized—Apollo Brand— Sheets, 6 or 8 feet long, 30 or 36 inches wide: 10-gauge, $3; 12-14-gauge, $3; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 lbs. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin—The combination seems to hold, and the price 45 to 50c., lower.

Tool Steel—Jowett's special pink label, 10½c. Cammel-Laird, 16c. " H.R.D." high speed tool steel, 65c.

Tank Plates—3-16 inch, $2.40 per 100 lbs.

Zinc—Spelter—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, December 9th, 1913.

Anvils—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¼ to 10¾c., anvil and vise combined, each $5.50.

Bar Iron—$2.50 base.

Bars—Crow $4.50 per 100 pounds.

Beams and Channels—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41.50, 118, 119, 172, 132, 145, 176.

Brick—Kiln run per M, $13; sewer pipe per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland—$2.40 to $2.50 per barrel.

Chain—Coil, 3 16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜ $5; 7-16, $4.75; ½, $4.50, 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper—Tinned, boiler, 26½c., planished, 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent. discount.

Dynamite—$11 to $13 per case.

Galvanized Iron—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20 $4; 18 $3.95; 16, $3.90. Queen's Head, 28, $4.90; 26, $4.70; 24, $4.80 22, $4.30; 20, $4.10 per cw

Iron—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26 gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7 80; 1½-inch, $9.35, 2-inch, $12.50; galvanized—½-inch $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50; cast share steel, $7.50; toe caulk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel—8½ to 15c. per pound.

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

AN EMERGENCY STOP-LOG APPARATUS

NOTES ON THE DESIGN OF THE SYSTEM TO BE USED ON THE TRENT CANAL — APPARATUS INCLUDES AN EIGHTY-FOOT SWING BRIDGE, TRAVELLING CARRIAGE AND WINCH CARRIAGE—ONE-MAN OPERATION.

THIS apparatus, as designed and used on the Trent Canal, is designed primarily to shut off the flow of water through the lock, should the gate be carried away, and also to serve as a coffer dam, should unwatering be necessary. It is an apparatus that is seldom used, but it must be instantly available, under all conditions of weather and at any time; hence great precautions were taken in its design to provide for any emergency. Also, as the distance between entrance walls is 33 feet a heavy log was indispensable, and its effect is necessarily carried through the structure.

The logs, as shown in Fig. 1, are of a built-up section and are provided with double rollers at each end to lessen the friction in raising and lowering. The total weight of each log is 5,800 pounds, and the pull required to raise is about 5,700 pounds at each end, for load and friction.

ELEVATION of BRIDGE, CARRIAGES and STOPLOGS

Fig. 1.

The component parts are swing bridge, travelling carriage, winch carriage, and winch, as may be noted in the diagram of Fig. 4 and in the other illustrations.

Fig. 2.—Normal Position on Entrance Wall.

Fig. 3.—Apparatus Swung Across Channel, Lowering Stop-Log.

The swing bridge is pivoted on the upper entrance wall, and is 79 ft. 3 ins. over all. It is composed of 2 plate girders, as shown, spaced 10 ft. 6 ins. centre to

centre, and is braced transversely on the shore or anchor end, but with no lateral bracing on the channel span where it is held with an end brace frame. This leaves a clear aperture sufficiently large that the log may be dropped through. This bridge is swung across the channel by means of a rack and pinion gear, as shown in the figure, and automatically locks into place.

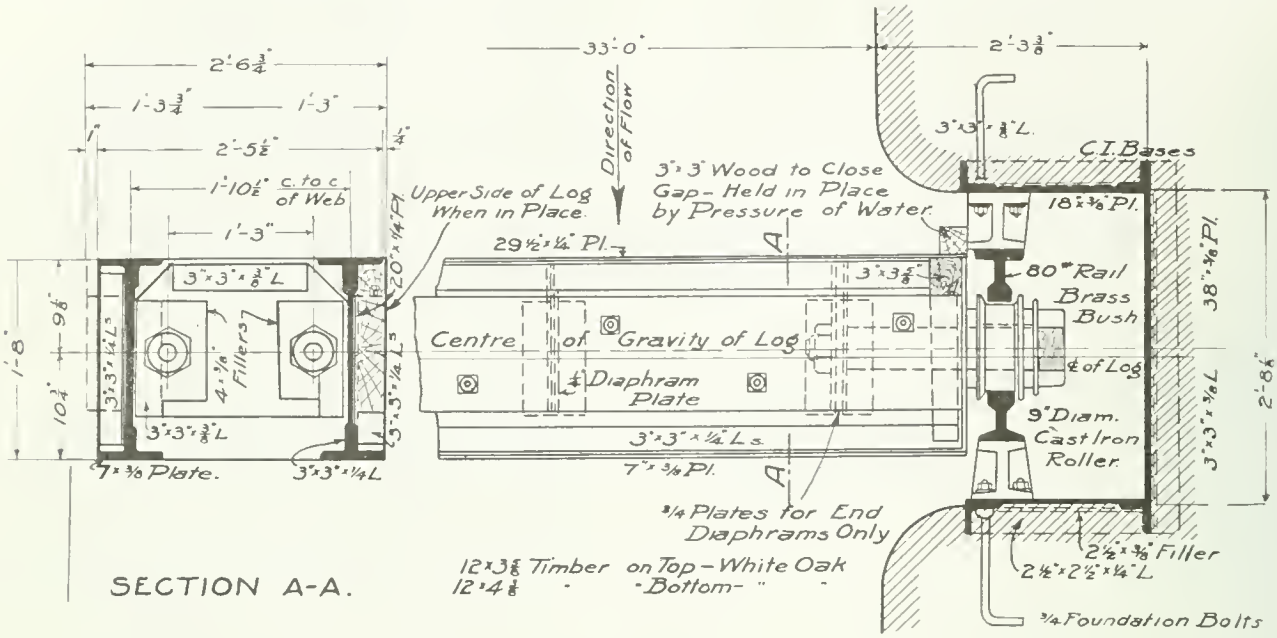

Fig. 4.

Rails are laid on this bridge on a 10 feet 6 inches gauge, and on these runs the travelling carriage, which can be run from one end of the bridge to the other by a crank-actuated mechanism. It is composed of two 12-inch I-beams at 31½ pounds, end braced.

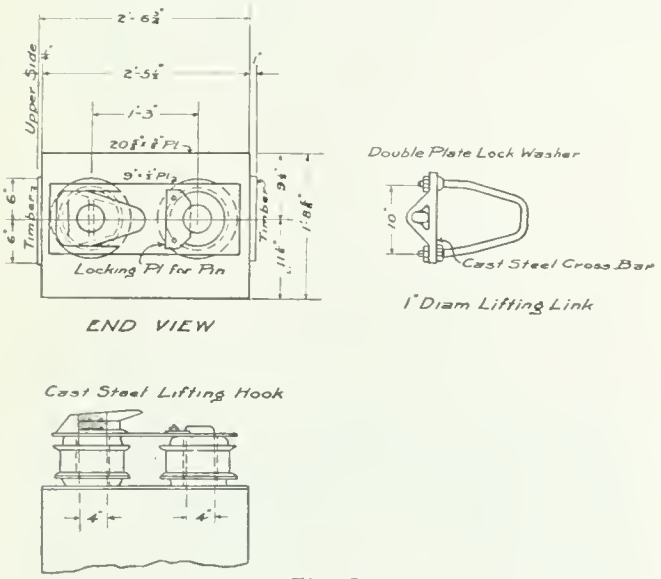

Fig. 5.

On I-beams fastened transversely on the ends of the travelling carriage the winch carriage runs. This carriage is made up of two built-up girders of ¼-inch plate and two 3-in. x 3-in. x 5/16-in. angles, and moves laterally the width of the travelling carriage. This carriage supports the winch. The method of operation is as follows: In its normal position on the upper entrance wall the four logs and travelling carriage rest on the shore end, and in this position the bridge is racked across the channel. The winch carriage is then centered over a log by its lateral motion, and by means of the winch the log is raised sufficiently to clear the floor. The travelling carriage is then run across the bridge to the automatic stop, the winch carriage again centered over the stop-log check, and the log lowered. This process is repeated until four logs are lowered and all flow stopped.

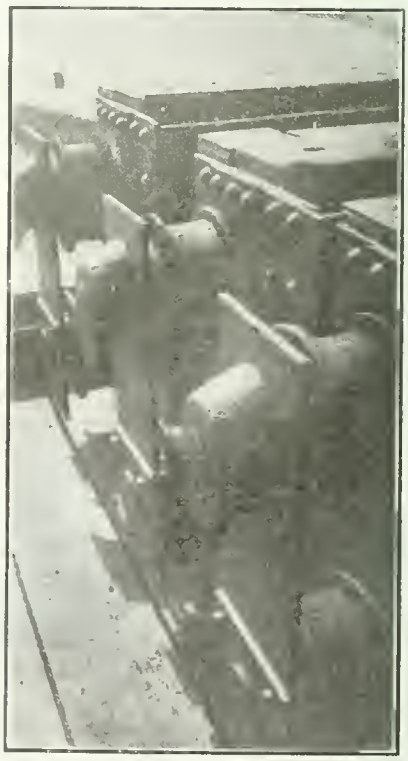

Fig. 6.—Detail of Ends of Logs on Bridge.

The whole operation can be performed by one man, but quicker gears are provided to be used if more men are available. As the majority of the reaches are of considerable size, both above and below the locks, speed in

shutting off the flow is not a highly important factor. However, the flow could be checked in twenty-five minutes, and completely shut off in an hour and a quarter.

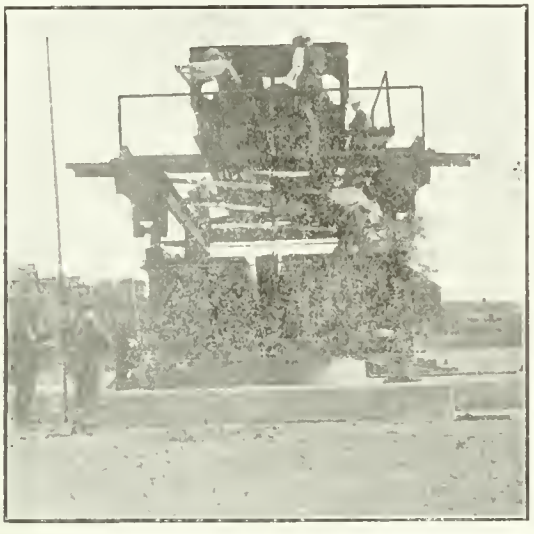

Fig. 7.—End View, Lowering Stop-Log.

The mechanism has been thoroughly tested. It has been satisfactorily operated by one man at night, and under all adverse conditions, and has given complete satisfaction.

The steel work was supplied and erected by the Dominion Bridge Co., Limited, and inspected in the shop and field by the Canadian Inspection and Testing Laboratories, Limited.

According to the United States Bureau of Standards, the melting points of fire brick are as follows: The most common fire brick, or those made of clay of which the main ingredient is kaolin, will melt at a temperature ranging from 2,831 to 3,137 degrees F.; bauxite brick, from 2,949 to 3,245 degrees; silica brick, from 3,092 to 3,101 degrees; chromite brick, at 3,722 degrees, and magnesia brick, at 4,929 degrees. These melting points, which represent the lowest temperature at which a small piece of the brick could be distinctly seen to flow, were determined in an electric vacuum furnace, the temperature being measured with an optical pyrometer.

The following is quoted from *Building Age;* "The freezing process in connection with excavations for the foundations of buildings appears to be something of a novelty in foreign countries, although many instances of it have occurred in America. The process, however, has recently been applied with economy and general satisfaction in Berlin, where the foundations of a large building had to be carried 10 ft. below the foundation of the abutting structures. As the latter were built on running sand, it was entirely out of the question to excavate for the new structure without special precautions, and the freezing process was adopted as an alternative to the pneumatic caisson method. Freezing pipes of 5-inch diameter were sunk around the space to be excavated and connected by headers with a brine pump and tanks. The cold brine was pumped through 1-inch pipes enclosed in the 5-inch pipes, and the brine was returned to the tanks through the latter. When the apparatus was put into operation the effect was to establish a stable barrier of frozen quicksand, permitting the foundation space to be excavated by ordinary means without difficulty."

TREE-PLANTING ON CITY STREETS.

By Fred L. Macpherson, A. M. Can. Soc. C.E.; A. M. Inst. C.E.,
Municipal Engineer, Burnaby, B.C.

THE aims and objects of this paper are not so much to submit any fresh or original ideas on the subject as more particularly to awaken the civic conscience to a sense of its duty and obligation towards, and to enlist the sympathy of the public in, a matter which so much affects its personal and civic welfare. That there is a close connection between our civic well-being and the condition of our public places is generally conceded, and the relationship becomes increasingly more apparent as our public places are made more amenable and pleasurable through beautifying with well-kept boulevards and ornamental trees and shrubs. Although the subject is one which generally has the sympathy and approval of public and private bodies, as well as the majority of individuals, it is astonishing how little specific information there is concerning it, and how very little action is taken to make the matter a practical reality. So far as the West is concerned, the movement is in its infancy. While many of our older towns and cities have achieved something towards this end, the majority of places either overlook or disregard this important feature of civic planning and beautifying.

Design of Streets.—The uses and purposes for which streets and highways are intended may be classified in the following order of importance, viz., traffic, building and aesthetic considerations. While utility must of necessity precede aesthetics, the latter demands and deserves more consideration and attention in street planning than it usually receives. Although a well-designed and well-constructed street primarily serves traffic and building conditions, beauty and harmony are necessary to give the street character and tone. Such an atmosphere is created by the scenic beautifying of streets and thoroughfares with impressive shade trees and well kept boulevards. The accomplishment is not the work or skill of the single individual, but is indirectly the combined results of many minds and activities. The co-operation of the landscape gardener, the engineer, and a sympathetic public is essential to achieve any successful and satisfying results in street beautifying. Wise discretion, unlimited enthusiasm, and infinite patience are all necessary to further any beautifying scheme, and even after the designer and gardener have done their parts one has to watch and wait for results, for nature objects to be hustled and must have her own way.

Important preliminary steps in any permanent scheme for tree-planting and boulevarding are (a) the establishment of the permanent grades of the streets, and (b) the classification of streets, as far as possible, according to traffic and building requirements, present and prospective; (c) the proper proportioning of the street width to equally suit traffic and aesthetic conditions. While street trees can frequently be planted before the permanent grading by making due allowance for same, unless for merely temporary effect, it is not wise to carry out any extensive boulevarding until the permanent grade of same is fixed.

Where street widths have not been generally established, such as in this neighborhood, at a minimum width of 66 feet, they should be standardized and classified as business, residential, or semi-residential streets, and any construction or beautifying carried out along systematic lines to typical designs. To derive the best results and prettiest effects it is very essential to have the travelled roadbed, the sidewalk and the boulevard symmetrical pro-

portions of the entire street. While as wide a road reservation as possible is generally desirable, it is not good policy from either an aesthetic or economic standpoint to construct more than a certain proportion of the street for traffic purposes, but obviously this will depend upon whether it is a business or a residential street. Too frequently in narrowing the boulevard the aesthetic features of a street have been sacrificed for its utility. Just as the relationship of the roadbed, sidewalk and boulevard should be equalized, so should the disposition of the public utilities, existing or projected, be carefully planned so that the finished street shall be complete and in harmony with its component parts. The lack of judgment and foresight is seen in our neighboring cities, where matured trees have been wantonly cut down to make room for curbs, and also where in cutting sewer trenches the larger roots of the trees have been cut through, practically giving the death-blow to the tree. While such unfortunate instances are not always avoidable, regrettedly they are more in evidence than might be with careful and scientific planning of the entire street and its component parts.

In strictly business streets, or in streets where the boulevards are not sufficiently wide, the planting of shade trees is not to be commended. It is a question of trees versus traffic—one must make way for the other or both will suffer. Hence, unless for purely temporary effect, it is not a wise policy to plant trees in spaces more urgently required for roadway or sidewalk.

It is the most common of errors to provide trees with too narrow a planting strip for full development. Besides, the effect being crude or incomplete at maturity, the trees tend to force out curbs and undermine walks. The width of the parking strip will be somewhat affected by the species of the tree, but, generally speaking, a minimum width of six feet is to be recommended. On narrower spaces it would be preferable to substitute evergreen shrubs for shade trees. A factor which sadly militates against any street beautifying scheme is the presence of pole lines. Indeed, in most localities it is, or becomes, a question of pole system or tree system, as both cannot exist together harmoniously, the merciless lopping of branches and the stumping of beautiful trees interfering with wires being within common knowledge. This matter might be better controlled by limiting the height of the lowest wires above the ground to, say, 25 feet, or, better still, by enforcing the use of underground conduits.

Advantages of Tree-planting and Boulevards.—Commercially good streets regularly and systematically lined with beautiful trees are a paying investment, tending to increase the value of property abutting thereon. They are the index of a city's character and well-being, and attract the attention of the casual visitor or the prospective investor. Who that has visited Portland, Ore., is not favorably and delightfully impressed by the restful and refreshing atmosphere of its tree-lined and rose-girt residential thoroughfares?

Physically, trees have a beneficent effect on the atmosphere. In the heat of summer they serve the double purpose of cooling the air with the evaporation from their foliage and of affording protection from the sun's rays. In affording protection from the glare of streets and in tending to diminish the nuisances arising from noise and dust, trees add materially to the comfort of residents. The restfulness to the senses which their verdure, form and proportion produces is also a healthful influence. In short, shade trees add to the beauty, health, comfort, and charm particularly of residential districts and lend an air of dignity and repose to the thoroughfares therein. Socially, tree-planting and boulevarding foster civic welfare and further "community efficiency." The efforts and results are inspiring and contagious—property owners copying examples become imbued with the idea of beautifying the streets in which they live, move and have a good deal of their being—until the entire community has become affected and enthused. Thus is the sense of civic righteousness increased, the public taste elevated, beautiful cities developed and good citizenship produced.

Disadvantages of Trees.—That shade trees have their drawbacks and disadvantages must be admitted. Especially in rural districts they keep the roads damp, and frequently they do not admit of a free circulation of air and wind. The constant dripping of rain from their leaves has also deteriorating effects on macadam roads. That shade trees interfere with traffic is not a valid argument against their adoption, but invariably a result of injudicious planting or inefficient maintenance. Reference has already been made to the destructive effects of tree roots on curbs, sidewalk and pavements, and mention might also be made of instances where sewers have been rendered useless, but most of the above drawbacks could be avoided by foresight in the designing and planting of the trees.

Kinds of Trees and Characteristics of Each.—Although there is such a large variety of forest trees, comparatively few of them are suited to or adaptable for street planting, and altogether it is somewhat difficult to find a tree possessing all the desirable qualities for street use. Generally speaking, trees should be selected particularly with regard to locality, climate, quantity and quality of soil, extent of space and special environment. Hence shade trees suited or appropriate for one locality, or even for one street, might not be equally suited or appropriate for the neighboring locality or street.

Of the above requirements the nature and extent of the soil are of great importance. The most suitable soil is one which contains neither too much clay nor too much sand, but a proper proportion of both. A hole about three feet deep, with an area of not less than a square yard, is desirable to produce the best results, but obviously the depth and area of the hole will depend greatly on the size and nature of the tree. In any event it is important that the young tree should have ample room in which to properly develop. For the very best cultivation the use of prepared soil is recommended. The following are the general essential qualifications of a good street tree: It must be hardy and not adversely affected by extremes of temperature; it must be able to withstand spells of drought, the dust of rural districts, and the smoke and soot, etc., of cities. The hardier the tree, the less susceptible it will be to the insidious attacks of insects and borers. It should have such recuperative powers as to quickly recover from malicious or accidental injury. The best tree should have a straight, clean stem, with shady foliage and a compact root system. To fulfil its chief function it should be graceful in full leaf or when bare in winter, namely, the length of leaf period should be as long as obtainable, the finest trees being those which leaf early in spring and provide shade and beauty well into the fall. A too rapidly growing tree, being usually soft and brittle and short lived, is not always desirable. A slow-growing tree, having better staying qualities and being less liable to be broken by the wind, is to be preferred where the planting scheme is to be of a permanent nature. A good tree should not branch too low—8 to 10 feet from the ground is desirable in the interests of traffic. The foliage of a good tree should be attractive, but not too dense to prevent a free passage of air and sunlight.

Whatever types of shade trees are selected—and the selection demands the care and discrimination of the experienced—the following precautions should be observed to ensure the trees flourishing and eventually producing the best and happiest results. The trees should have been well nourished and tended in the nursery. They should not be planted in the street until they are about eight feet high, with the stem at least two inches thick. The stem should be clean and as straight as possible, and the entire tree symmetrical in shape. Trees about eight years old are preferable. If the ground and soil are not suitable, they should be made so; special treatment will be necessary in hardpan, where it is very essential that a hole should be made sufficiently wide to accommodate the roots of the tree in a well-advanced stage. Trees should not be planted any deeper than their original nursery marks indicate. Most trees flourish best when the tops are trimmed about a foot when planted, although many experts contend that young trees are best left to their own resources. It is generally wiser to erect proper wind protection shields, which will further tend to safeguard the trees from the ravages of animals and mischievous children. The age, nature and kind of tree and its environment will determine this matter. As moisture is next in importance to air in the nourishment of young trees, the roots should be well watered, especially during the first and second summers after planting. Sprinkling the foliage is also beneficial in removing the dust and soot therefrom.

In cities or districts where trees are to be planted extensively the establishment of corporation nurseries (which could be conveniently done in actual or prospective parks in play-grounds) will make for uniformity, efficiency and economy in tree-planting.

Setting-Out and Planting.—The setting-out and planting of shade trees are highly important matters so frequently ignored as to minimize the initial, and particularly the final effects. The spacing of shade trees will naturally depend upon their variety and nature and the extent of the boulevard. As a general rule they should be planted so far apart that at maturity they will not meet. Planting too close is the most prevalent error in setting out shade trees. In their desire to have immediate effect the inexperienced too frequently plant trees so close together that it is only a question of time before well-developed trees have to be cut down to make room for their neighbors. For permanent results it is better to err on the safe side and plant trees too far apart. Where temporary effect is the main object in view, trees and evergreen shrubs might be planted alternately and the shrubs transplanted when the trees begin to expand and require the maximum of space. Generally speaking, a spacing of from 30 to 40 feet should be adopted. As regards the distance from the property line, this will depend upon the width and layout of the street, but where possible a distance of from 10 to 12 feet is to be recommended.

To produce the most pleasing and aesthetic effects, shade trees should be planted at equal distances apart and on a line as parallel as possible to the curb or centre line of the street. It is a matter of opinion, but especially on the narrower streets trees should be planted alternately on opposite sides of the street. The practice of planting one kind of tree for one block and an entirely different type of tree on the next block on the same street, as has been adopted on the Grand Boulevard in North Vancouver, is not commendable, as naturally the different trees grow at different rates and in different shapes, and the results at maturity are unsymmetrical and the effects patchy at the best. Several sorts of trees of varying ages, sizes and shapes should not be adopted, although two kinds of a similar nature might with aesthetic advantage be planted alternately on the same street. Streets named after trees should, as far as practicable, be planted with trees to correspond. Very pretty after-effects can be produced if trees are properly and symmetrically disposed of at street intersections so as to produce the maximum of shade. Shade trees should not be planted in a careless and haphazard manner. As has already been said, the combined skill, taste, and experience of the engineer and the landscape gardener are essential to secure the most finished and most artistic effects. Truly, tree-planting and tree preservation is a science and not what it is too frequently thought to be, the easy, simple matter for the unskilled.

Maintenance of Trees.—Such necessary and important matters as the care and maintenance of shade trees are so often neglected for so long a time that frequently many originally fine trees are found to be beyond recovery. Trees should not be left wholly to their own resources, for with due care, constant watchfulness and regular attention they will flourish oftentimes in unfavorable conditions. Instances of trees having been stuck in rather than planted are too common, and in such cases, instead of being a thing of beauty and a joy forever, as often as not the carelessly planted and untended trees soon present a lifeless appearance and a sorry spectacle. Young trees should be regularly and properly trimmed, preferably in the late fall, all broken or rotten branches being removed. Any injuries to, or disease in, the bark should, however, receive prompt and careful attention whenever found necessary.

Trees affected by moths or insects should be sprayed at the proper season to keep the nuisance and blight from spreading. Where borers are the source of trouble special treatment will be necessary, "capital punishment" being, of course, most effective. Cavities in older trees, in which water and dirt lodge, tending to hasten decay of the tree trunk, have been successfully treated and the life of the tree thereby increased, by carefully filling with concrete. Reference has already been made to the necessity for regularly watering young trees during the summer months. Altogether, the "tree doctor" is an essential in successful tree culture.

In his Presidential address to the British Concrete Institute, Mr. E. P. Wells dealt with some practical matters connected with concrete construction. He urged the necessity of keeping a more careful watch on the cement used than had hitherto been done. During the past year it had been found in several cases that cement had been "air-slaked" to such an extent that it was almost useless for reinforced concrete work. Instances were mentioned of faulty storage by manufacturers' agents and of careless handling by builders, and it was suggested that cement should be brought on to the works in casks and stored in air-tight bins. Reference was made to the unsightly contraction cracks that took place in reinforced and other forms of concrete construction, but so far no remedy had been found. Some experiments had been promised to see whether it was not possible to stop cracking to a large extent, and if satisfactory the results would be given to the Institute. The extended use of reinforced concrete work in the Colonies, notably in New Zealand, was referred to, as was also the apparent slackening in the home production of steel. Touching upon the difficulty of obtaining assistants capable of designing reinforced concrete work, he stated that much of the inadequacy of reinforced concrete design was attributable to the inexperience and want of proper technical training among structural engineering draughtsmen.

LEGAL SUGGESTIONS RESPECTING ROAD CONTRACTS.*

By William Law Bowman, C.E., LL.B., New York City.

ETYMOLOGICALLY and technically the word "contract" should mean an agreement enforcible by law. "The Law of Contract may be described as an endeavor of the State . . . to establish a positive sanction for the expectation of good faith which has grown up in the mutual dealings of men of average rightmindedness." How do our present public contracts for road construction and their interpretation by officials satisfy these old definitions? As a part of the great work of properly linking our states and their cities and towns with uniformly good roads, it is incumbent upon us to better and if possible make uniform the contract conditions respecting the construction work and to secure that co-operation and esprit-de-corps between officials, engineers and contractors which alone will give us the best roads for the least money with a minimum of trouble and wasted energy. It has been wisely remarked that "you get only what you pay for" and in the long run that is as true in road construction work as in any other field.

Let us first consider some general principles respecting states, municipalities and roads which should be known in order to appreciate the special subjects which will be considered.

The state is a sovereign body and as such is not responsible by action at law or in equity. There are a few isolated cases holding that when a state goes outside its governmental capacity, it may then be used in the Federal Court. No dependence, however, can be placed upon these decisions by a contractor. The result is that a contractor with a state has no way to enforce his contract rights nor to secure redress against official oppression unless the state legislature has provided therefor. The best and usual plan is the formation by the legislature of a court or board of claims to hear and determine claims against the state, its departments and boards. One state allows a contractor to sue it, provided the legislature passes a special bill for the specific matter. The value of that right is well illustrated by a statement made to the writer by an offending official that when he got through with the matter I would have to have more political influence than he thought I had in order to get such a bill through the legislature. It is also the general rule that in such instances the offending official himself is beyond the legal reach of the contractor. Thus it is that except in those states having a court or board of claims, official oppression and even financial ruin can be honestly or dishonestly caused without any hope or prevention or redress for the contractor. A so-called agreement where the contractor depends solely upon the action of an official and his engineer should not be called a contract. It violates the true meaning and our understanding of that term. This inability of a contractor to enforce his contract rights or even to demand fair play and justice cannot but be detrimental to good economical road construction. Under such circumstances the work becomes political—only favorites dare bid or accept contracts—and the other results of political work naturally follow.

Due to this fact that most states could not and still cannot be compelled to live up to their contract conditions, the terms of a state contract have been considered practically unimportant by the contractor. He knew that he must follow the direction the plans and specifications called for. While conscientious and honest officials and engineers predominate in state work, yet they at times need the restraint which a chance to be heard by the contractor affords. Furthermore, the atmosphere and the mental attitude of all concerned is bad in such a situation. Those opposed to granting the contractor this right to properly and legally present his claims before a disinterested court or party will be interested to know that even so great a sovereign as Emperor William of Germany last year lost an action to one of his tenants in the German Supreme Court over the value of certain improvements. Therefore, unless a state has a board or court of claims open at all times to those contracting with the state, its departments and boards, or unless it provides for a submission to an impartial and disinterested arbitrator or arbitrators any changes in the present state contracts that are discussed or suggested will, of course, be useless except as they may influence the controlling official. In this connection it has been very noticeable that both the judges and the juries favor the state or municipality when they are sued. This is even found where it is necessary to construe the iron-clad terms and conditions of our present day one-sided agreements which are required to be signed by those desiring to engage in public work and where it would be expected there would be some sympathy for the contractor. In all seriousness, then, it is submitted that there seems to be no logical reason why the contractor should not be given an opportunity to get a square deal if he believes he is not being fairly or honestly dealt with.

Municipalities are the legal creatures of the legislature, and their powers and rights must be found in the law creating them. Throughout this paper the term municipalities will signify cities, counties, towns, boroughs, road districts, etc. As a governmental agent, a municipality is immune in respect to mere errors of judgment, but in its ministerial capacity it is liable for consequences of negligence and maladministration. As regards plans for public improvements some courts attribute negligence to a municipality in the adoption of a defective plan and the test of the liability of a municipality which causes injury is not the fitness of the engineer, but the efficiency of the work. Where a defective plan is the result of bad faith or oppression or is so clearly unreasonable as to inflict needless injury, a court may enjoin performance, or, if the work is completed, hold the municipality responsible.

Roads are in the control of the state. In doing road work a municipality acts as the agent of the state performing a public duty imposed by law. On this account those dealing with either roads or municipalities must ascertain the legislative acts pertaining thereto as a basis for any serious investigation. In determining the powers or rights conferred by such statutes the investigator must remember that the wording of the law will be strictly adhered to and that the tendency is to restrict powers granted and to deny any implied powers or rights.

Since a contract may be either wholly void or voidable at the option of the state or municipality unless certain preliminary steps are properly taken, and since in such instances it usually results in a total or partial loss to the contractor of his compensation for work done and material furnished it is essential that a brief warning in this regard should be given.

*Read at American Road Congress, Detroit, Mich., Sept. 29 to Oct. 4, 1913.

With respect to roads; the proceedings to acquire the land; the report upon the advisability of a road; the estimate of the cost; the description of the road; the survey and resurvey; the proper sanction of the voters or taxpayers; the proper formation and action of the boards or courts, etc., all must be in compliance with the statutes and laws pertaining thereto. In addition the actual preliminaries to the contract itself must be regularly and legally complied with:—A proper and sufficient appropriation or available funds; a proper advertisement for bidders; a proper letting to a proper party; a properly constituted board or official acting strictly in accordance with its or his authority; a proper bond for performance, etc. The contract itself must be in the required form properly executed, for the purposes allowed by the special statute, with proper persons entitled both to give and to have such contract and in accordance and in conformity with the preliminary reports, plans, specifications, survey, description, etc. As has been previously stated, failures, omissions, or negligence on the part of any of the state or municipal officials or agents in the above respects may cause the contractor to lose his compensation for work done and for benefits actually conferred by the contractor. There are some decisions and some statutes which are based on equity to prevent such unjust enrichment of such bodies at the expense of a contractor, but it is not safe to rely on such law in any particular instance. The general rule may be likened to the ancient rule of "caveat emptor" or, as it might be expressed here, "let the contractor beware." This warning, while primarily for the contractor, should be taken to heart by the official who is trying to do right and be honest, since usually he is the unfortunate party that causes the contractor's troubles and losses.

Contracts.—As we have already seen, most present day state contracts for road construction are not really "contracts," because of the inability of the contractor to sue thereon. In addition, I have also seen one state contract which stated that "all right or rights of any action at law or in equity under or by virtue of this contract and all matter connected with it and relative to the same are hereby expressly waived by the contractor." Practically the same result is accomplished by other states and especially by municipalities by the requirement that upon or before final payment the contractor must execute a release in full of all claims arising out of or by reason of the work done and material furnished under the contracts. Is this *good* faith in the dealings of men of average right-mindedness? I cannot conceive of but one answer to this question. The remedy then is simple. Provide either fair and disinterested boards of arbitration to pass upon a contractor's claims or provide a court of claims and eliminate any waiver of appeal to such arbitrators or court and the general release as a condition precedent to final payment from all road construction contracts. In other words, give the contractor a chance for a square deal upon a two-sided mutually agreeable contract. In passing, it might be noted that the United States Government is probably the worst offender in this matter of unfair and objectionable clauses, including that requiring a release, and it is setting a disgraceful example for the states and municipalities.

Satisfaction Clauses.—It is probably a safe statement that there is no state or municipal contract in use to-day which does not provide for the "satisfaction" of some official, board or engineer or all combined. Is this a necessary, fair and honest requirement in road construction contracts, or is it merely a club to compel the contractor to do what the official or engineer wants regardless of the plans and specifications?

In most states it has been properly held that this requirement merely necessitates work satisfactory to the mind of a reasonable man. Thus if the work has been performed substantially in compliance with the contract, the law will hold the official, engineer, etc., to be satisfied. With plans and specifications so clear and concise as they generally are in road construction, and especially with the work required to be done "under the direction" of an engineer and under constant inspection, it would seem that legal satisfaction would be presumed in 99 out of 100 cases, and hence the use made of this requirement in such states would be merely to bluff or bulldoze the contractor. In no way does it improve the requirements of the plans and specifications.

In such a state as Pennsylvania, where work can be held unsatisfactory by the official or engineer even though the plans and specifications are rigidly adhered to and where only honesty of purpose is required, the result of such a contract requirement may be heartbreaking. Under the guise of dissatisfaction I have known an official in that state to deliberately violate every essential provision of an agreement and to settle at his own figure with the contractor; or, in plain English, to rob the contractor not only of his contract right but also of thousands in money with no redress. A contractor who accepts state work in a state where this personal satisfaction of private taste in road construction is required must understand that he is at the beck and call of the official or engineer regardless of his contract requirements and conditions. What could the contractor in such a state do when he has to satisfy not only the engineer in charge, but the Road Commission and a state board? Suppose the work satisfied one and not the other two, or two and not the third party?

Our considerations recommend that "satisfactory" requirements be dropped from road construction contracts as either unnecessary, harmful or unfair and as not being a sanction for the expectation of good faith between men of average right-mindedness.

Contract Work.—In looking over many of the latest forms of road construction contracts it is noticeable that there is a very decided improvement in the manner and method of setting forth the contract work and specifying what is variously designated as alteration, addition, miscellaneous, or extra work, etc. Road work is now generally specified in various units and a price bid for each respective unit. In one such contract we find this definition: "Extra work is any work in connection with the execution or completion of the contract for which no price is included in the proposal sheets and contracts." Compare this simple and concise statement with a New York City form which had different requirements for ordering additional work as differentiated from extra work, the distinction not being stated and being such that there would be times when the average engineer or contractor would not know to which class the work belonged to. Result—the contractor would be refused payment for additional work done pursuant to extra work requirements or vice versa.

In the same regard why should a contractor, as is now frequently demanded, be responsible for unknown or underground conditions? Just lately in New York City a paving contractor found a lot of rock above grade which should have been taken out by a prior grading contractor. Under notice to bidders to examine the site, etc., the

Court of Appeals held that the plans of the completed grading contract on file in the city offices did not constitute a representation to bidders of the condition of the road bed and hence the paving contractor had to do this work of grading without extra compensation.

Let us, then, have definite contract units of work at unit payments clearly specified, and provide payment for any other work necessary which may arise either at the unit prices or, as is becoming popular, upon a percentage basis. This latter method seems a fair means of providing for extra work as hereinbefore defined but the contract must specify exactly what is to be considered the "cost" upon which the percentage is based, as there is great difference of opinion on the subject. For example, in one state, the statute provides for certain construction work at cost plus 15%. There being no provision against subletting, the actual work was done by subcontractors at a fixed price. The "cost," as sustained by the highest court, included the cost to the contractor for the work as agreed and paid to the subcontractor, the contractor's overhead expenses for supervision, engineering, office rent, etc. In this way the state actually paid 53⅓% on the actual cost of labor and materials at the job which is the popular conception of the word "cost" in percentage contracts. The rules of law applicable to percentage contracts are the same as those to the ordinary lump sum contracts. Under proper contract conditions with definite plans and specifications and with honest officials and contractors, contracts on the percentage basis of "cost of labor and materials at the job" would, in my opinion, give as wide scope for competitive bidding and should give better results in actual construction work. It should do away with many of the conflicts now common between the official, the engineer, or both, and the contractor. The tendency would also be to give closer competition between the large corporation with heavy overhead charges and the small concern with practically no such expenses. There would seem to be no question but what in the long run this would be less expensive to the municipality because it would tend to cut out the contracts with enormous profits and at the same time lessen the broken contracts because no contract should be given out for less than the defined "cost" price. This is merely a suggestion in passing, but I should like to see it given a fair trial.

Duties of the Engineer.—Under most of our road construction contracts the engineer takes his time-honored dual capacity of agent for the state or municipality and arbitrator between the contracting parties. It has been noted that if the contract provides that the engineer will make an estimate and issue a certificate he will often do so where he may refuse if such wording is not used. There is no question but what the engineer is given too much "discretion" under our present contracts. In road construction work there would seem to be no excuse for a lack of definite plans and specifications which of themselves should reduce the engineer's discretion to a minimum.

There always will be objections to the salaried or paid engineer of a state or municipality acting as an arbitrator without appeal as is the result accomplished by practically all state and municipal contracts. Upon the wording of such contracts some courts have even gone to the extent of holding the contractor but not the state or municipality bound by the engineer's decisions within the scope of his authority. Clearly such a result is unjust. In addition to this, state and municipal contracts are so replete with oppressive or "club" clauses for the engineer that a contractor knows he must take care of that official one way or another. It has been well said that no man should be placed in such a position where bribery and graft is often the easiest and cheapest solution of differences or disputes. Whether or not the engineer is an arbitrator depends upon the strict wording of the pertinent clauses of the contract. All such clauses will be strictly considered and no implied powers will be given the engineer. Where an engineer is made an arbitrator he must remember that he has greater powers than the judges on the bench, because he may intentionally decide contrary to the law and still have his judgment stand. On this account an engineer's decisions should be beyond reproach. The fact that in the exercise of his duties as arbitrator he cannot be held legally responsible for lack of skill, carelessness and even negligence should create an ambition to merit the honor bestowed. The engineer should never forget that he is, under present day clauses, taking the place of the court and that his action may close the door to either party to appeal from his decision. Professional honor and reputation often depends more upon the engineer's action in such matters than upon his pure engineering knowledge. However, the engineer must know that he cannot ordinarily deprive the contractor of his right to judicial construction of the contract after it has been performed so far as such construction involves matters of law. These considerations show us that the engineer holds under our present day construction contracts an almost impossible position for a human being. Would it not be better to relieve him of some of these onerous duties? Experience seems to show that better feeling, better work, and co-operation between the engineer and contractor may be secured by more precise, concise and definite plans and specifications, and the elimination of all unnecessary "discretion" and "arbitration without appeal" clauses respecting the engineer.

Construction of Contracts.—Since we cannot expect any sudden change in present road construction contracts, this paper would not be complete without a statement of some of the most general legal principles which should govern the actions of officials and engineers even if the contractor cannot sue or get a fair hearing for his side. Since all state and municipal contracts emanate from the contracting official the ordinary rule is that the contract provisions should be construed most strongly against the author. Especially is that so when such construction is necessary to save a contractor from fraud and injustice, or where, as in these contracts, one party is at the mercy of the other. The following instances where municipalities have been held responsible in damages on account of the actions and orders of officials and engineers should be known and avoided:—

(*a*) Mistakes in lines, grades, elevations, plans or specifications or directions whereby the contractor had either to do additional work or do over work already done.

(*b*) Requirement that the contractor do the work in a way not called for by the contract, entailing more expensive work than would customarily or otherwise be entailed.

(*c*) Requirement that the contractor do over work already done properly or repair or maintain the same unreasonably.

(*d*) Requirement that the contractor do work not within his contract as contract work.

(*e*) Refusal to permit contractor to perform work called for by his contract.

A substantial performance of a contract creates a situation where the contractor is entitled to his full con-

tract price less the expense of supplying the omissions and defects. From a study of cases all over the country the following rule would seem practical for contracts under $25,000. Provided the contractor has honestly attempted to complete his contract, and particularly when he has followed the directions of the official or engineer, and when the omissions or defects do not pervade the whole work or make the object of the parties impossible or difficult of accomplishment, or when the usefulness or value of the construction is not materially impaired, and provided the cost or reasonable value of correcting such defects or omissions does not exceed 6% of the contract price, then there has been a substantial performance. No practical working rule can be given for contracts over $25,000. Substantial performance also excuses the production of an engineer's certificate.

In this connection it is important to note that in correcting defects, supplying omissions or completing a contract the state or municipality becomes bound by the terms of the contract and its plans and specifications. For example, if the contract permitted the use of native stone the state cannot use trap rock and expect to charge that against the contractor. In such instances a burden is imposed upon the official to complete the performance in good faith pursuant to all the contract provisions and with reasonable care and regard to the rights of the contractor. There seems to be a tendency on the part of some officials to make an example of a contractor who has defaulted. Their chief object often seems to be to spend all the retains and, if possible, all they think they can collect on the contractor's bond. This is neither legal nor honest. The completion work must be done diligently, and the damages mitigated as much as possible. High-priced men cannot be used for cheap labor, nor can completion be delayed until market prices have risen. Thus it has even been held that a municipality was bound by the date of completion when it assumed a contract.

If a contract calls for liquidated damages for delay after a specified date, such damages are waived or are not recoverable by the state or municipality where they render the contract incapable of performance within the specified time or where they assume as agents of the contractor to complete the contract. Similarly if the delay after a specified date is caused, both by the state or municipality and the contractor, the liquidated damages cannot be apportioned. It has been held that a city cannot retain a substantial sum under the guise of liquidated damages for delay when in fact only nominal damages have been sustained. Where the liquidated damage clause falls, then actual damages caused by the contractor must be proved as an offset. There is still one very important matter pertinent in this respect. Where a contractor follows detailed plans and specifications and the directions of the engineer and completes any part or all the work there should be no deductions for variations from the contract since the parties have practically construed the contract as one for work in accordance with the engineer's directions and such construction must prevail over the literal meaning of the contract. Also under these same conditions and circumstances a contractor is not responsible for a result nor is he responsible for any defects or repairs (except where there is a repair clause) beyond those required by the failure of the contractor's materials or by the contractor's own work. In other words, a road contractor usually does not warrant the road as capable of standing any particular traffic, etc., that should be determined by the plans and specifications.

Naturally the most important thing to the contractor is prompt payment, not only of his partial but also of his final payment. It is a general rule of law that a failure of a state or municipality to pay an instalment on the due date causes a breach of contract which relieves the contractor from further performance and enables him to collect the contract price or reasonable value of all work done to date. The failure of the engineer to make his estimate and issue his certificate may not excuse a failure to pay partial payments even if they are required to be made only upon engineer's certificates. The refusal of an engineer, under ordinary circumstances where there has been work done, to make his estimate and issue his certificate in time so that the contract payment can be made is of itself presumptively fraudulent. Again, it is often found to be the case that the engineer refuses to act upon the direction of the official, which, of course, is collusion, and which excuses the production of such certificate. It is a rule of law that an engineer's certificate will not be considered as a condition precedent to a partial or final payment unless it is definitely and distinctly stated so to be in the contract. The control of the money bag is often supreme and in this way engineers and officials have it in their power to make or break a contractor. A reputation of an engineer for prompt and fair estimates and of an official for prompt payments is sure to result in lower bids and better construction work.

Having considered these few most important matters and with an understanding of the legal principles involved cannot we in the future have justice and equity and not vengeance, spite or bossism in road construction work? The result of such a change, where it is necessary, cannot but be beneficial to all concerned.

Repairs.—There seems to be a tendency in some of the present day road contracts to require a contractor to maintain the road for a specified length of time, usually one to five years. Is that a good and economical requirement? Does it not, to a certain extent, restrict bidding and contracting to local parties? Are not the unit prices and hence the contract total largely increased to take care of an unknown amount of repairs? Is there not a gamble on that matter? The best of roads require constant inspection and repairing to keep them in shape. That work should be done either under a strictly repair contract or by the state or municipality itself. This criticism, of course, is more applicable to country roads as differentiated from city streets.

Summary.—In a late article of mine advising architects respecting employment by state or municipalities the following rules were formulated which would seem pertinent here:

(1) Know that the municipal corporation is acting pursuant to the law creating it.

(2) Know that your contract does not cause the indebtedness of the municipality to exceed its constitutional or statutory limit.

(3) Know that your contract does not exceed a limit above which advertisement and acceptance of the lowest bidder is required or that proper advertising, awarding, etc., has been done.

(4) Know that assessments or taxes to pay for public improvement work which include your compensation are valid.

(5) Know that the board or official employing you do so in the proper legal method required by the oct incorporating the body or by the charter or by the local rules governing such body.

(6) Know that funds are available or a specific appropriation made by the proper authorities to pay you before proceeding with your contract work.

(7) Have your contract in writing and know that it is worded properly.

(8) Have and put everything in writing and act only upon the strict wording of all contracts.

(9) In state work ascertain first if there is a state board or court of claims; if not you must depend on the official honesty and integrity of the official with whom you deal. Remember personal honesty and official honesty are contradications in some officials.

(10) Never consider or do any public work without first consulting competent legal advice.

While the above advice for the contractor will give him some knowledge of his position in a road contract, yet it does not protect him from the many abuses now possible under such contracts. Those must be corrected by honest, conscientious officials who will countenance only the same character of engineers. Contracts and general specification conditions for road work must be drawn solely for that class of work and not copied slavishly from ancient documents used for buildings, etc. There must be no discrepancy between the contract clauses and the general conditions or other parts of the specifications. Unit prices for unit quantities of specified work with full details in the plans and specifications or cost plus percentage contracts for definite work with opportunities for honest, competitive bidding and awards to lowest bidders are essential. All unnecessary "satisfaction," "discretion," "warranty," "final and conclusive decision," "waiver of damages," "waiver of claims," "waiver of right of action," etc., clauses and other similar oppressive or "club" clauses for the official and engineer must be eliminated. They certainly are anything but a sanction for the expectation of good faith . . . in the mutual dealings of men of average right-mindedness. Lastly, and most important, the agreement between the parties must be made a real contract by giving the contractor the power to assert and prove his claims before a competent court or board.

It is probable that next year a commencement will be made with the construction of the railway bridge between Rugen and the mainland, which will be the longest in the world, exceeding even that over the Hohangho, with its 3,580 yards. The cost of this great engineering work is not expected to amount to more than $5,000,000, or less than a third of that on the Forth bridge. When the bridge, which, it is said, is to include a track for pedestrians, though none for road traffic, is completed it will substantially shorten the journeys between Berlin and Hamburg on the one hand, and Stockholm and Christiania on the other.

The value of the mineral production of Queensland for 1912, according to the annual report of the Minister for Mines, was £4,175,355, including coal. The increase over the preceding year was £514,292, due to the stimulating influence of high prices for metals, together with a noticeable advance in the yield of copper, tin and other minerals. The value of the gold yield for the year was £1,477,979, less than that of copper, and a decrease from 1911. Mount Morgan continues to be the leading mine. Of the copper mines, the Cloncurry is the foremost producer, making a contribution of 10,435 tons. The total copper production was 23,120 tons. While prospecting for tin was active, there were no new discoveries of importance made during the year. The tin-ore production was 3,230 tons, valued at £364,503. The silver production was 569,181 oz. Lead, tungsten, manganese, bismuth, molybdenite, opal and other gems were also produced.

A NEW PROCESS OF CLEANING PRODUCER GAS.

IN 1902 Mr. H. F. Smith, Mem. Am. Soc. M.E., instituted a series of investigations to determine the nature of the mechanical impurities present in producer gas from bituminous coal with a view to devising more effective methods for their removal. These investigations have since been continued and have resulted in the development of a commercial apparatus involving some new and interesting principles which are described in the following article, recently presented as a paper to the American Society of Mechanical Engineers, and appearing in the Journal of the Society:

The tar and other mechanical impurities present in raw bituminous producer gas are in an extreme state of subdivision. The number of particles present is so great and the quantity of gas to be handled in commercial plants so large that the problem presents more than ordinary difficulties. The effectiveness of the ordinary types of mechanical gas washers and purifiers leaves much to be desired. The primary object has accordingly been to produce equipment that will be capable of yielding gas of a higher degree of cleanness than obtainable by ordinary

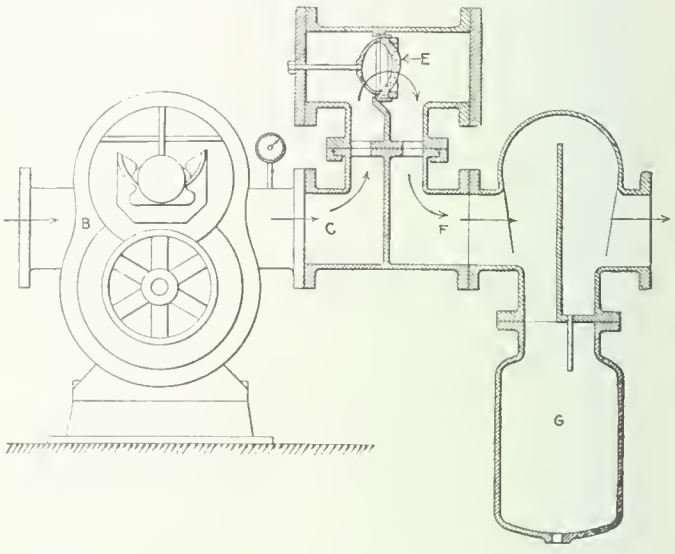

Fig. 1.—Static Scrubber Layout.

methods. The apparatus in its present stage of development can be readily understood from Fig. 1.

The raw producer gas, on leaving the producer, is first cooled to a point where the tar vapors are condensed by being passed through a primary cooler or condenser. From this the gas is carried into an ordinary rotary gas pump *B* which delivers the gas under pressure into the main *C*; it is then delivered through a porous diaphragm *E* and discharged from there into the main *F*. A sump or separator *G* is provided in which the tar accumulates.

The structure of the diaphragm *E* is a matter of considerable importance for the successful carrying out of this process and the materials used seem to have an important bearing on the operation of the equipment. The diaphragm must be sufficiently porous to permit the gas and tar to pass freely, otherwise it will soon become blocked with deposits from the gas and fail to operate. Many materials may be used for this purpose, but at present spun glass is preferred. The glass fibres are not only entirely unaltered by chemical action but seem to possess the necessary physical properties for the successful carrying on of this process. The spun glass in the form of ordinary glass wool (which should be carefully distinguish-

ed from slag wool, as the latter is not practicable for this purpose) is built into the form of a uniform diaphragm and is retained between two metal screens. The density of the diaphragm can be regulated by the quantity of glass used and by the degree of compression maintained between the metal screens. Ordinarily, this diaphragm is made up to a thickness of approximately one-quarter of an inch. The diameter of the diaphragm must be adjusted in accordance with the quantity of gas to be treated. Ordinarily, about 400 cu. ft. per hr. can be handled for each square inch of diaphragm area. No tar is retained in the diaphragm, both tar and gas being discharged together.

In passing the diaphragm an important change in the physical state of the tar occurs. On the entering side the tar exists in a large number of minute particles, ordinarily known as tar fog. In passing the diaphragm these particles are caused to coalesce so that on the discharge side the tar particles are of relatively large dimensions, so large in fact that they can no longer be carried forward in the gas current and immediately separate out by gravity. All that is necessary for the complete separation of the tar from the gas is to provide a sump, or drip, into which the precipitated tar can drain.

It appears to be possible to secure almost any desired degree of gas cleanness simply by regulating the pressure maintained across the diaphragm. In ordinary commercial operation, it is found that a difference in pressure of from 2½ to 4 lb. will give a degree of gas cleanness that is ample for any commercial requirement. Thirty cubic feet of gas cleaned in this way can be passed through a white filter paper without producing any discoloration.

The distinction between this process and the process of purification by filtration can be best shown by outlining the conditions essential for each process:

(1) In filtration the best separation is secured when the rate at which the materials to be separated pass the filtering medium is slow. One of the substances to be separated remains in the filter.

(2) In the process in question good results can be secured only when the velocity of the gas passing through the diaphragm is very high. Nothing whatever remains in the diaphragm.

At low velocities the gas will pass through the porous diaphragm used in this apparatus without any apparent alteration, and the degree of effectiveness of cleaning is directly related to the velocity of flow. For example, the degree of cleanness produced with the velocity of flow resulting from 1 lb. pressure, and when the velocities are as low as those produced by a pressure of a few ounces only, there is no perceptible change in the tar content of the gas after passing through the diaphragm.

No water is used in connection with this process except that required to cool the gas. As a consequence there is no production of tar emulsion and the water flows from the condenser perfectly clear. The tar separated by this process is practically water free, and can accordingly be used for any purpose to which cool tar is adaptable. One sample of tar drawn directly from the receiver showed on distillation a water content of less than 1 per cent. as compared with from 20 to 60 per cent. which is ordinarily present in gas producer tar from mechanical washers. The calorific value of producer tar from Hocking coal is approximately 15,800 B.t.u. per lb., about 140,000 B.t.u. per gal.

For the maintenance of continuous operation the tar must be sufficiently fluid to pass through the porous diaphragm without creating undue resistance, and therefore it is necessary to maintain the temperature of the gas entering the diaphragm at a point that will reduce the viscosity of the tar to as low a point as is consistent with complete condensation of the tar vapors.

It is also apparent that this apparatus would not be well suited to use on gas containing large quantities of lamp black or for purification of gas from coals yielding very heavy viscous tars. For high volatile coals, however, such as are found in Ohio, Indiana and Illinois, and for lignite, it has been found in practice to be thoroughly practical and effective. It is possible that further developments may extend the applicability of this method to conditions which are not now considered practical.

The exact method by which this tar extractor operates has not been conclusively demonstrated. Two theories have been advanced which may possibly cover the ground: The first and most obvious is that the tar particles are precipitated by being brought into direct collision with the threads or filaments of the porous diaphragm.

That this does not constitute a complete explanation of the process is indicated by the fact that the material of which the porous diaphragm is constructed has a marked bearing on the effectiveness of the process and would indicate some action other than simple mechanical collision. For example, if the porous diaphragm is made up of steel wool instead of glass wool (the physical structure of the diaphragm being as nearly as possible the same in each case) the process does not operate with anything like the effectiveness secured with glass diaphragms. It would seem that the possibility for collision would be the same in both cases.

A phenomenon, first observed by the writer in 1902 during some experimental investigations, gives further credence to the theory that there is some action other than pure mechanical collision. If the gas is caused to pass through a small tube with perfectly smooth walls, as for example a tube of glass, no particular precipitation of tar occurs as long as the velocities of travel are slow. However, as the velocities increase to a point where there is considerable friction between the gas and the surface of the containing tube a heavy precipitation of tar occurs on the surface of the glass. This fact leads to the conclusion that friction is in some way concerned in this process, since the probability of mechanical collision is rather remote. Since friction between rapidly moving gases and enclosing tubes is known to be productive of electrical phenomena, it was assumed that this might possibly have some bearing on the action of this process. In fact this interpretation was the one first placed upon the phenomenon observed in 1902 and an effort was made to work out a tar extractor along this line.

An experimental apparatus was constructed at that time in which heavily charged electrodes were employed to precipitate the tar particles and it was found that fairly effective results could be secured. Experiments along this line continued for a number of years, but the difficulties in the way of producing commercially practical apparatus caused its final abandonment. The rate at which the tar particles could be moved through the gas under the influence of moderate potential gradients was very slow. It was accordingly necessary to use exceedingly high potentials in order to secure effective results. With the spacing of electrodes of approximately 1½ in. a potential dif-

ference of 25,000 to 35,000 volts was required for effective precipitation. On account of the difficulty of maintaining proper insulation under these potentials and on account of the great danger of serious injury to an unskilled operator in manipulating apparatus of this kind, this method was not considered practical. It was noted, however, that by decreasing the distance between the electrodes a very marked decrease in potential was observed. Accordingly another experiment was devised which will perhaps throw still further light on the method of operation of the process under consideration.

A series of electrodes was prepared with exceedingly small intervening spaces, and placed in connection with a source of direct electro motive force, the potential difference between the plates being much below that required to produce any ionizing discharge. It was found that at these small distances distinct cleaning effects could be obtained without ionization. Maintenance of the electric charge from external sources was troublesome owing to electrolytic short circuits occurring between the electrodes through deposits of tar and moisture from the gas. The fact, however, that there is a distinct attraction exerted by electrified plates at comparatively low potentials (which is sufficient to cause a precipitation of tar particles from gases) leads to the conclusion that if the distance between the electrodes could be reduced sufficiently the potential differences required for effective electrical action would be very small.

It would seem possible, therefore, that in addition to the effects of mechanical collision there might be a distinct electrical attraction exerted by the glass fibres constituting the porous diaphragm which are located at microscopic distances from each other and which are undoubtedly subjected to some electrification from friction with the gas currents. If the possibility of such electrical action is considered, the increased effectiveness of glass as compared with steel for the construction of the porous diaphragm is satisfactorily explained. That friction of this nature is capable of producing electrical disturbances of considerable magnitude is well established.

It might be interesting in this connection to refer to recent experimental determinations by Professor Dolezalek of Charlottenberg, Germany, who showed that the friction of liquid benzol against the sides of containing pipes may set up potential differences of as much as 3,000 volts. As a very small fraction of this potential would be sufficient to account for the observed effects, it would seem only reasonable to presume that in addition to the effects of mechanical collision which undoubtedly exist, there is some electrical action which is of material aid in causing the coalescence of the particles of tar fog.

Whatever may be the correct explanation of the phenomenon, its effectiveness and practical importance are beyond question. The first commercial equipment of this kind has now been in continuous operation for approximately 18 months. This outfit is handling gas for a producer gas power plant of approximately 1,000 h.p. capacity. The second commercial equipment is handling approximately 900 h.p. producer gas, and has been in daily service for approximately ten months. The largest single installation is an equipment for cleaning 200,000 cu. ft. of gas per hour. This installation is operated in connection with a single producer unit which is of interest because it is one of the largest single unit plants ever installed in the United States. This producer has an effective grate surface of 250 sq. ft. and is rated to gasify 3,000 lb. of Illinois bituminous coal per hour.

SUCTION CONVEYERS.

By Reginald Trautschold, M.E., New York City.

THE economical handling of ashes from the furnace in power stations, etc., has always presented one of the most difficult of conveying problems, for the hot ashes cause rapid deterioration of any apparatus that they come in contact with, and the fine dust is detrimental to bearings, links and all pivoted connections as well as any surfaces of contact as it works into or lands on surfaces and produces destructive abrasive wear of the moving parts. Quenched ashes may be even more destructive owing to chemical properties of the ashes, so that the handling of ashes, either as they drop from the grates or after being sprayed with water to lower their temperature, cannot be performed with maximum economy by any of the continuous conveying or elevating systems of mechanical handling. Systems of the intermittent type are usually more satisfactory, owing to the fact that the ashes may be thoroughly cooled before delivery to the conveying apparatus, but ordinarily some car system or even more manual system of handling the ashes proves the most satisfactory in the long run—at any rate, in installations where but a relatively small quantity of ashes have to be disposed of. In a power house developing less than 2,000 h.p., the skip-hoist, a heavy bucket elevator or some car system is generally the most economical equipment for the handling of the ashes, but for larger plants —from 10 to 15 per cent. of the coal consumed being converted into ashes that have to be removed from the ash-pits—the suction conveyer proves an economical system to install.

The suction conveyer may also be employed for the handling of cement clinkers, comparatively fine materials of any description, etc., which, on account of their heat, chemical properties, fineness, etc., prove unsuitable for conveyance or difficult to handle by the ordinary mechanical types of conveyers. Even fine coal and similar materials have been economically and efficiently handled by the suction conveyer, but as the logical field for its operation is the handling of ashes, cement, lime, wood chips, etc., and the progress made in the development of this comparatively new method has been largely limited to ash handling installations, a description of a typical installation of such character will serve to show the advantages and convenience of the system.

Primarily, a suction conveyer consists of a heavy steel or cast iron duct in which the material to be handled is carried; an overhead storage tank of steel or concrete, in which a partial vacuum is maintained by an exhaust fan, to which the conveyer duct discharges; and a water spray in the storage tank for cooling the ashes, precipitating the fine dust, etc. In an ash-handling installation, the duct, consisting of an ordinary pipe, runs directly in front of or under the boilers below the boiler room floor, and is provided with a small intake in front of or under each grate. These intakes are each provided with an easily removable but tight-fitting cover which is kept closed except when the conveyer is being charged at that particular intake. On leaving the boiler room, the conveyer duct rises to the top of the elevated storage tank to which it discharges downward, the discharge pipe or conveyer duct extending downward in the storage tank for some little distance. From the storage tank, usually also from the top, an exhaust pipe extends to an exhaust fan which sucks the air from the storage tank, creating a partial vacuum throughout the conveying system. Below the ex-

haust pipe from the storage tank and above the discharge end of the conveyer duct, a water pipe in the storage tank delivers a fine spray over the material from the conveyer duct, quenching the ashes and precipitating the fine particles of dust and thus preventing their being drawn up into the suction pipe by the exhaust fan. As a further precaution against damage to the exhaust by fine particles of material that might not be precipitated by the water spray, the exhaust pipe is frequently equipped with a special dust collector.

The operation of the system consists simply in removing the cover from an intake and bringing the ashes or other material to be handled to the opening, the air rushing through this open intake then picks up the material and carries it to the storage tank. The velocity of the air through the conveyer duct being at a maximum at the centre of the pipe and decreasing towards the walls of the conveyer duct, the tendency of the load is to remain in suspension while being swept along by the rushing air, thus reducing the wear on the sides of the duct to a minimum—in fact, no wear or deterioration of the conveyer duct pipe on straight stretches is apparent even after several years' operation, the rapidly moving air preventing the gathering in the duct of any moisture or other agents that might have injurious effects. Any depreciation of duct, on level stretches, must therefore come from the outside and this can, in large manner, be guarded against and prevented. At elbows, however, the abrasive wear is great, the particles of material striking the elbow obliquely and being deflected back into the path of the moving air. This scouring action is so marked that ashes will wear away an ordinary elbow in short time. To overcome this drawback, the elbows are constructed with removable backs of manganese steel, carborundum or other substance possessing high resisting qualities to abrasive wear which may be easily and relatively inexpensively replaced as they wear out. Such wear-resisting elbows are placed wherever the general path of the conveyer duct changes direction. The scouring effect of the load on the elbows, which is so great as to bring them to a high state of polish, tends to keep the reduction in speed of air and load through the duct, due to a sudden change of direction, at a minimum.

For a simple installation of small capacity, the rotary exhauster for removing the air from the storage tank consists of a centrifugal fan, while for a larger and more complex system a cycloidal blower is employed. The exhauster discharges to the atmosphere and is in operation for only long enough to create the necessary vacuum in the system before the load is delivered to the conveyer duct intake and while the conveying is in actual productive operation. At other times, the vacuum in the system gradually disappears and the material handled may be removed from the storage hopper, the emptying gate of the hopper discharging to wagon, car or other conveying system, as the case may be. Though the conveyer duct of a suction conveyer may have several intakes, any one of which may be used to load the conveyer, the discharge from the duct must always take place into the storage hopper of the system. In the case of handling ashes, this is no great drawback, as, ordinarily, no further handling of the ashes is necessary, the ashes being discharged from the storage tank to the vehicle removing them from the plant. When handling other material than ashes, such as coal, other systems of conveying machinery or some type of car is necessary for delivering the material from the storage tank to storage or to whatever point it is to be used. If material is placed in storage before being used, it can frequently be reclaimed by the suction conveyer through a duct running under the stor-

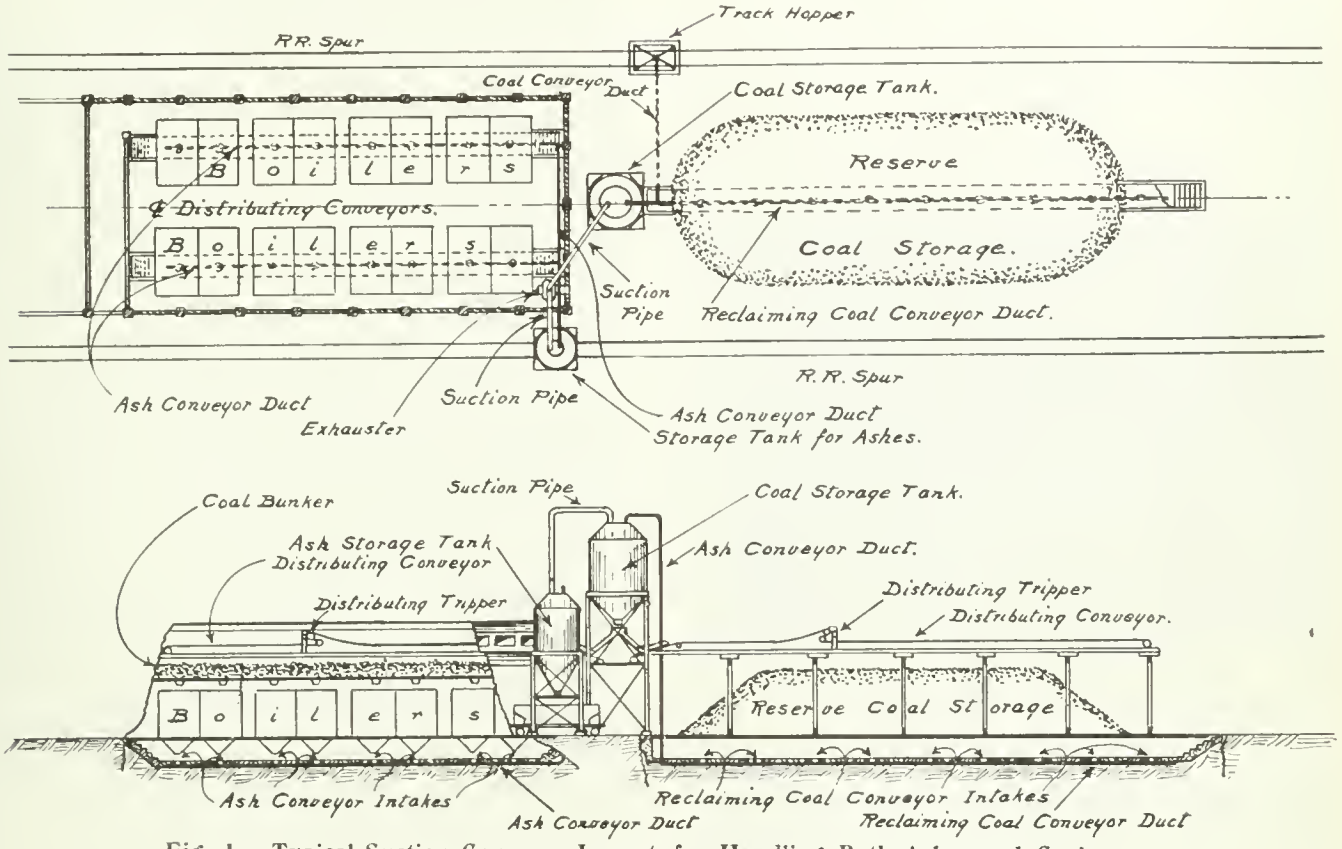

Fig. 1.—Typical Suction Conveyer Layout for Handling Both Ashes and Coal

age pile and discharging to the same storage tank serving for the conveyer duct handling the material before it is put in storage, distribution to point of consumption, either before the material is placed in storage or after it is reclaimed, being performed by other type of conveyer or car.

Capacity.—With a fixed velocity of air through the conveyer duct, quantity of air that can be removed by a centrifugal exhauster varies with the square of the diameter of the duct and as the degree of vacuum that can be maintained also depends upon the rate of air removal, the carrying capacity of a suction conveyer varies directly with the square of the diameter of its duct. The diameter of the conveyer duct being used to designate the size of the conveyer, Table XIII. gives the carrying capacity of the various sizes of suction conveyers handling ashes and handling fine coal. The range of sizes of conveyers given in the table is somewhat greater than those which may be termed standard, for a 6″ conveyer, the smallest standard size, has an ash-handling capacity sufficient to care for a power plant of from 2,000 to 4,000 h.p. capacity, while the largest standard size, 10″, can handle all the ashes from a 30,000-h.p. plant. The capacity of the standard sizes of conveyers, 6″, 8″ and

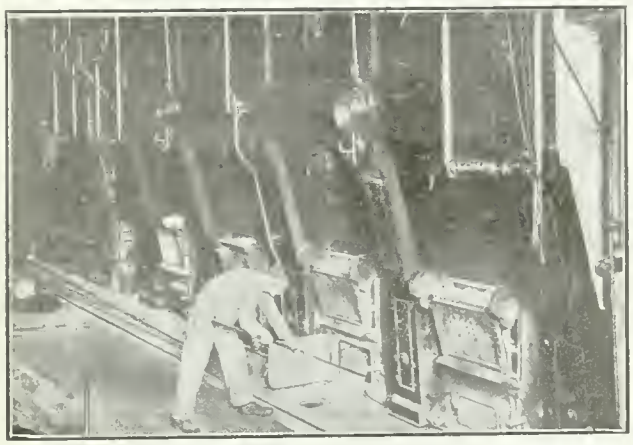

Fig. 2.—A Suction System in Operation. Conveyer Duct is Directly Beneath the Floor.

10″, are compiled from results actually attained in practice and show that not only does the capacity of the system vary with the square of the size of conveyer, diameter of its duct, but that the capacity appears to vary directly with the respective weight of the material handled. Though this appears to be so for ashes and fine coal, it is doubtful if such a relationship can be taken as a law. However, for the materials particularly adaptable for handling by the suction system such relationship is doubtless sufficiently general for all practical purposes. Expressed in the form of a convenient equation the relationship existing between capacity of the conveyer and its size (diameter) and weight of material handled is given as Formula XXVI.

Table XIII.—Capacity of Suction Conveyers in Tons Per Hour.

Diameter of duct. Size of conveyer.	—Capacity of handling— Ashes. Tons.	Fine coal. Tons
4″	2.60	3.70
6″	5.85	8.00
8″	10.35	14.10
10″	16.30	23.05
12″	23.50	32.25

$$W = 0.00385\ w'd^2 \quad \text{.....Formula XXVI.}$$

Where:—

W = Capacity of suction conveyer in tons per hour.
d = Diameter of conveyer duct in inches.
w′ = Weight of material handled in pounds per cu. ft.

Though the foregoing capacity table and formula are approximately correct, it must be remembered that suction conveyers, which may be classified as belonging to the class of conveying apparatus of the continuous type, cannot be operated continuously and the results attainable in practice must be based on very occasional service. That is, such a conveyer must necessarily be idle much of the time, so, in choosing the proper size to install, the capacity per hour must be taken as the maximum rate during the occasional periods of operation.

Power Requirements.—In the consumption of power, the suction conveyer differs from any other type of conveyer in that the length of conveyer has practically no effect upon the power requirements, these depending almost entirely upon the size of conveyer and therefore upon its capacity. This peculiarity is due to the fact that after a certain degree of vacuum is created in the system no more power is required to maintain such vacuum in a long conveyer than in a short one. Leakage through intakes that are not tightly closed do tend to destroy the vacuum of the system, but this leakage is so slight compared to the inrush of air through the intake that is being used for loading that for all practical purposes the length of the conveyer has no effect upon its power requirements. A long conveyer, it is true, requires more air to be withdrawn to create a given vacuum, but the volumetric contents of the duct per foot is so small compared with the contents of the storage tank from which the air must also be exhausted that it takes practically no more time to produce the partial vacuum in a system 1,000 feet long than in one of half that length. The height to which any material of given weight can be raised by suction is fixed, but the maximum lift for any substance suitable for conveyance by the system is well in excess of the elevating requirements of any ordinary installation, so that the power requirements of any suction conveyer may be simply expressed in terms of its diameter and the weight of the load handled. (See Formula XXVII.).

$$d^2 = \frac{260.4\ W}{w'}$$

$$HP = 0.555\ d^2 = \frac{144.52\ W}{w'} \quad \text{.....Formula XXVII.}$$

HP = Average HP required
d = diameter of conveyer duct in inches.
W = Weight of load conveyed in tons per hour. (Table XIII.)
w′ = weight of material conveyed in pounds per cu. ft.

By far the most expensive pieces of apparatus required for a suction conveyer are the exhauster, storage tank with its accessories and the dust collector, and the cost of these depends not upon the length of the conveyer but upon its size. The cost of the balance of necessary equipment, including the conveyer duct, suction pipe, intakes, elbows, etc., varies with both the size and length of the conveyer, but form such a relatively small part of the total cost of equipment that there is really little difference in the cost of the average installation of any given

size. That is, the length of conveyer for the average installation may be neglected in figuring an approximate initial cost for the installation—it being understood, of course, that the length of conveyer be neither extremely short nor unduly long. Neglecting the question of length, then, its cost will vary closely with the square of its diameter, or with its carrying capacity. The average relationship existing between initial cost and size of conveyer and capacity of conveyer, deduced from an examination of actual costs of numerous installations, is given as Formula XXVIII.

$$C = 145\ d^2 = \frac{37{,}750\ W}{w'} \quad \text{.....Formula XXVIII.}$$

C = Initial cost in dollars.
d = diameter of conveyer duct in inches.
W = Weight of load conveyed in tons per hour—capacity, Table XIII.
w' = weight of material conveyed in pounds per cu. ft.

Net Operating Cost.—To arrive at the economic value of a suction conveyer, represented by its net cost of operation, a number of assumptions must be made, as this method of handling materials is of such recent development that there are no authentic records from which depreciation, expense for attendance or the cost of incidental supplies can be calculated. However, as these expenses are all practically limited to those in the operation of the exhauster and as records of similar centrifugal fans and cycloidal blowers are known, calculations may be made that should be approximately accurate in the majority of installations. (See derivation of Formula XXIX.). The consumption of power, or the amount of power chargeable to each ton of material handled, is also difficult to ascertain accurately. Careful tests have ascertained the power consumed during actual operation under capacity (see Formula XXVII.) but this type of conveyer must necessarily operate under frequent and considerable variations of degree of load, all of which require approximately the same supply of power as does also the conveyer when carrying no load at all but maintaining the necessary degree of vacuum. Assuming that during 20 per cent of the time that the exhauster is in operation, the conveyer carries its capacity—a record that careful attention to efficient operation should make possible—the average net operating cost of the system, per ton of material handled or other unit, may be expressed in the form of a simple equation. (See Formula XXIX.).

$$\text{Average cost of equipment per ton capacity} = \frac{145\ d^2}{NW}$$

Average hours of operation per year at capacity = 180 = N

Average cost of equipment per ton capacity = $0.806\ d^2/W$

Cost of Power:

Net = $0.555\ d^2\ P_o/W$

Actual = $5 \times 0.555\ d^2\ P_o/W = 2.775\ d^2\ P_o/W$

Attendance—

Average = $1.850\ d^2\ P_o/W$

Supplies—

Average = $2.375\ d^2\ P_o/W$

Interest 6% total cost
Insurance 1%
Taxes 2% ¾ cost
= $0.0685\ d^2/W$

Depreciation, renewals, etc.
Dep. acc't., 10% of dep.
= $0.0265\ d^2/W$

Net operating cost = $0.0950\ d^2/W + 7.000\ d^2\ P_o/W$

$$\text{N.O.C.} = \frac{(95 + 7000\ P_o)d^2}{1000\ W} \quad \text{.....Formula XXIX.}$$

N.O.C. = Net operating cost per ton handled, in dollars.
d = diameter of conveyer duct (size of conveyer) in inches.
W = Weight of load (capacity) conveyed in tons per hour.
P_o = Price (cost) of power per horsepower.

Example:

Conditions—
Size of conveyer .....8″
Material handled .....Ashes
Cost of power .....$0.02 per HP.

W = 10.35 tons (Table XIII.).

$$\text{N.O.C.} = \frac{(95 + 7000 \times 0.02)\ 64}{1000 \times 10.35} = \$1.424 \text{ per ton of ashes.}$$

The conditions of the example cited are typical of a coal-burning power house of about 8,000 hp. capacity, and the work entailed consists of conveying the ashes a total distance of some 500 to 1,000 feet and placing them in an overhead storage tank from which they can be easily removed for final disposition. The total cost of performing such operations is equivalent to a charge of about 14¼ cents for the disposal of ashes per ton of fuel consumed. In such a plant, the expense of disposing of ashes ordinarily amounts to from 15 to 25 cents per ton of fuel consumed, depending upon the conveying system employed. The difference between such rate and 14¼ cents does not, however, indicate the full economic value of the suction conveyer. The cleanliness, convenience and reliability of the system adds greatly to its real worth and it is unfortunate that the high initial cost of a suction conveyer installation and its consumption of power prohibits its use for small plants. When handling heavier materials, or at such service as permits its more continuous operation, the net cost of operation per ton handled is reduced, and further development and progress in this method of conveyence will, without doubt, open many new fields in which the peculiar advantages of the suction conveyer will enable it to show decidedly higher financial economy in operation.

The list of the various awards made at the International Building Exposition, held in the city of Leipzig, Germany, during the past summer has now been received. Among those who were awarded the gold medal of the Exposition and the various silver and bronze medals and diplomas is found quite a number of United States firms, mostly of a commercial nature, but it is gratifying to find near the end of the list three engineering organizations and an individual engineer. The Alsace Lorraine prize was awarded the Board of Water Supply of New York, while Gustav Lindenthal, the American Bridge Company and the Strauss Bascule Bridge Company, of Chicago, were awarded the gold medal of the city of Leipzig. Mr. Lindenthal, in connection with the American Bridge Company, exhibited plans of the Hellgate Bridge, etc., while the Strauss Company had a small exhibit of models and photographs of Strauss bascule and lift bridges, which, however, attracted considerable attention, owing to the large number of successfully completed structures which the exhibit represented.

SALT IN CONCRETE.

In July 31st issue of *The Canadian Engineer* an article appeared containing a summary of observations made by the U.S. Bureau of Standards upon the action of salts in Alkali and sea water on cement and concrete structures. The reader is referred to the conclusions therein, in connection with the following report of a series of tests to determine the effect of sodium chloride and calcium chloride, separately and together, upon 1:2:4 concrete were made at the University of Wisconsin during the winter and spring of 1912 by Messrs. H. E. Pulver and S. E. Johnson, instructors in mechanics. The test pieces were cured at temperatures of from 60 to 75 deg. Fahr. and below freezing. The results have been published in the "Wisconsin Engineer" by Mr. Pulver.

All mix was by volume and the salts were dissolved in the mixing water. The test pieces were 4-in. cubes, and those cured at a temperature below freezing were broken after fourteen and sixty days, while those cured at normal room temperatures were broken after fourteen, sixty and three hundred and sixty days. Four pieces were tested at each age for each batch of concrete. Atlas Portland cement was used, and to prevent variation in the quality it was mixed thoroughly in the beginning and a sufficient quantity stored in airtight cans.

The test curves show that as the percentage of NaCl is increased there is a nearly straight line decrease in the strength of the concrete cured under normal conditions. The effect of NaCl alone, when added to concrete cured at low temperature, is probably to reduce the freezing temperature, and hence retard the freezing of the concrete, thus permitting of its setting and hardening. The curves show an increase in strength for the addition of NaCl up to 12 per cent., after which there is a decrease. It may be that beyond 12 per cent. the weakening of the concrete due to the excess of NaCl more than offsets the strengthening due to the reduction of the freezing temperature.

When $CaCl_2$ alone is added to the concrete, cured either at normal or low temperatures, the effect is to increase the strength up to about 4 per cent. $CaCl_2$, at which point the maximum strength seems to be obtained. This increase in the strength of the concrete may be due to the acceleration of the setting of the cement by the $CaCl_2$. Serious disintegration was observed on the surfaces of the cubes cured at low temperatures with 6, 8 and 10 per cent. of the $CaCl_2$. This disintegration did not appear on any of the cubes cured at normal temperature or where NaCl was used.

With concrete cured at low temperatures, the best effect seems to be obtained by using both NaCl and $CaCl_2$ in the mixing water. It was noted that a 2 per cent. $CaCl_2$ and 9 per cent. NaCl mixture appears to give the most satisfactory results. For concrete cured at low temperatures this mixture gives about as much strength as any of the mixtures tried, and for the concrete cured normally there was not a very great reduction in strength due to the addition of the salts in those percentages.

All tests were made with only one brand of cement. It is probable that there would be some variation in the results with other brands, but it is not thought that this variation would be great enough to affect the general conclusions. It is also possible that some brands of common salt might contain a sufficiently high percentage of calcium sulphate to affect the results to some extent.

TRAFFIC SUITABLE FOR VARIOUS ROAD SURFACES.

The Massachusetts Highway Commission, after some years of study and experiment, has made the following statement of the effect of traffic on roads and the necessity of legislation governing the relation of width of hard tires to the loads carried by them:

A good gravel road will wear reasonably well under a daily traffic composed of 50 to 75 light teams, 25 to 30 loaded one-horse vehicles, 10 to 12 loaded two or more horse-drawn wagons, and 100 to 150 automobiles. With a larger number of automobiles, the gravel should be oiled. The oiling presents what is spoken of as a "blanket surface" consisting of heavy asphaltic oil and sand. If the oil be applied hot, the blanket surface will last 3 to 5 years, if cold, it must be renewed every year.

Oiled gravel will stand fairly well under 75 to 100 light teams, 30 to 50 heavy one-horse vehicles, 20 heavy wagons with two or more horses, and 500 to 700 automobiles daily.

Waterbound macadam will stand under a daily traffic of 175 to 200 light teams, 175 to 200 heavy one-horse vehicles, and 60 to 80, perhaps more, heavy wagons with two or more horses. If even 50 to 100 automobiles per day go over the road at high speed dust-layers will be serviceable. With a really good dust-layer the road will stand 300 to 500 automobiles a day, although the stones will wear.

Waterbound macadam with an oil and sand blanket, applied hot, will be economical with 150 to 200 light teams, 75 to 100 heavy one-horse vehicles, 25 to 30 heavy wagons with two or more horses, and automobiles, up to 1,400, or more with fewer teams and with 50 or more motor trucks. The large number of automobiles seems to keep the oil rolled down when it would cut up and crumble without this traffic.

Dr. Alfred Thompson, M.P., stated recently that this year in the Yukon more than $5,000 in gold was taken out, chiefly by the Guggenheims and the Boyles. The production of gold by individual miners was comparatively a negligible quantity. Most of the gold was taken out by dredges, the two big companies each operating four mammoth diggers. Two of the dredges operated on the Boyle concession are among the largest in the world. Power for operating the dredges was furnished by the development on the Yukon River, installed and controlled by the Treadwell people. During the low-water period in September a steam power plant installed some years ago at Coal Creek, a short distance down the river from Dawson, was brought into service, so that the dredges were operated for full six months.

The main line of the Transcontinental will total a trackage of 3,550 miles from Moncton to Prince Rupert; but that does not comprise the whole system by any means. There are to be many branch lines taking care of settlements in sections of the country hitherto unprovided with transportation facilities. These lines, upon which, in some instances, a beginning has been made, will amount to over 1,000 miles of added trackage, and will tap large territories hitherto inaccessible. These branches, or lateral lines, are to serve new populations, which will follow them in line of the system, and then spread over the new country served by spur trackage, which will connect them with the great artery through which their products will be brought to the centres of population in older Canada.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MINING, MUNICIPAL, HYDRAULIC, HIGHWAY AND CONSULTING ENGINEERS, SURVEYORS, WATERWORKS SUPERINTENDENTS AND ENGINEERING-CONTRACTORS.

Present Terms of Subscription, payable in advance.
Postpaid to any address in the Postal Union:

One Year	Six Months	Three Months
$3.00 (12s.)	$1.75 (7s).	$1.00 (4s.)

OTTAWA'S WATER PROJECT AND ENGINEERING FEES.

The letter, which appears in another column, relating to the nature of the contract between the City of Ottawa and Sir Alexander Binnie in connection with its Gatineau Lake water supply scheme, is misleading in a general way and does not do justice to the Ottawa civic authorities. The writing of this letter was evidently occasioned by the editorial comments of a New York journal which apparently created an erroneous impression by associating statements and comparisons respecting percentage fees, with the Binnie contract.

In *The Canadian Engineer*, October 16th issue, an article appeared outlining the proposal accepted by the City of Ottawa to bring its water supply from the Gatineau Lakes, a distance over all of fifty miles, at a total cost approximating $8,000,000. It was later announced that Sir Alexander Binnie, a well-known English engineer, whose recommendation had been adopted, had been retained by the city as designing and supervising engineer of the entire work.

In the letter, and in the New York editorial as well, the impression is conveyed that the engineer is receiving a fee of $75,000 for the privilege of drawing $1,000,000 for "engineering and contingencies," and of allowing a lawyer to buy $500,000 worth of land. From a $400,000 contract to carry out an $8,000,000 scheme, it is deduced that the fee is on a five per cent. basis, which is pronounced "good." Further, the editorial urges engineers who have become discouraged at the lack of financial recognition of the engineering profession, to take heart.

It was never proposed to pay Sir Alexander Binnie on any percentage basis whatever. The $400,000 fee includes $250,000 to pay assistant engineers and inspectors, while $50,000 more will no more than provide for the working out of the plans, specifications, salaries of draftsmen and office staff, etc.—leaving approximately $100,000 as the engineer's remuneration. The city had the alternative of paying the assistant engineers and inspectors, and leaving to Engineer Binnie the financing of drawing office and other disbursements. From this proposition he was to receive $140,000, and, as in the other case, his own remuneration would approximate $100,000. The city accepted the former proposal as the better of the two, although it thereby created apparent food for discussion.

As it stands, $100,000 is a good fee for an engineer on an undertaking such as this. For, analyzing this expenditure of $8,000,000, deducting the $500,000 for land purchase, on which small engineering service is required, also $976,000 for engineering and contingencies, and $3,600,000 for the gravity flow steel pipe line, on which the cost of design and supervision of construction is also comparatively small, (but essential, nevertheless, as it is a vital question with Ottawa), we have $2,900,000 left to be expended on construction work requiring a considerable amount of high-class engineering ability. But if Ottawa pays its engineer $100,000 for his services on this alone, what can we say by way of criticism, when Toronto has paid out $72,000 for engineering services in connection with the filtration plant that has cost $778,000 all told, designed and supervised by a New York engineer? Ottawa is taking no chances on the possibility of unsatisfactory work. It is not to be inferred that we parallel the case with that of the Toronto filtration plant, or that the expenditure connected with the latter was wasted. However, in Nov. 27th issue of *The Canadian*

Engineer we reviewed specifications for a new mechanical filter plant large enough to handle Toronto's entire requirements; and the name of the New York engineer who drew the $72,000 for the old (two years old) Toronto plant is not connected in any way with the design of the new plant.

Mr. Macdonald's reference to the new intake pipe and aqueduct has recalled an instance which may or may not have been in the minds of the Ottawa City Council. An editorial observation in a previous issue of the journal referred to, that two previous supply schemes were voted down by Ottawa, presumably owing more or less directly to the fact that each had been worked up by a New York engineer, may or may not have had its weight. With the first instance, Mr. Macdonald associates the word "disastrous." In the second, an engineer referred to has designed and superintended the construction of a number of Canadian engineering enterprises, and if there is a single one that has been popularly pronounced satisfactory, we have yet to learn of it, and it is our belief that the City of Ottawa cannot outdo us in the enumeration of instances.

Ottawa has an excellent source of supply in the Gatineau Lakes. The city is sorely in need of it. A satisfactory job is essential to the scheme. It is a big undertaking and it is worth money to the city to know that the man to carry it out entertains no scruples in the matter of remuneration.

Ottawa's recognition of engineering ability is not to be depreciated but praised. Deduct, however, the $75,000 which has been regarded as questionable, and who would care to undertake the work?

EDITORIAL COMMENT.

The last of a series of eight articles by Reginald Trautschold, M.E., appears in this issue of *The Canadian Engineer*. The series entitled "The Mechanical Handling of Materials," has created a good deal of interest among manufacturers, engineering-contractors, mining and structural men. The separate instalments, with the date of issue of each, are as follows:—

"Mechanical Handling of Materials," August 21st.
"Spiral or Screw Conveyers," September 4th.
"Belt Conveyers," September 18th.
"Belt Conveyers" (Part II.), October 2nd.
"Bucket Conveyers," October 16th.
"Handling Materials by Bucket Carriers," Nov. 6th.
"Skip Hoists," November 20th.
"Automatic Railways," December 4th.
"Suction Conveyers," December 18th.

* * * *

The piercing of Mount Royal within a few hours of the time at which it was estimated some months ago that the headings of the tunnel would meet, took place on the morning of Dec. 10th, and a train went through in the afternoon. How successfully this work has been carried out is indicated well in the extreme accuracy with which the headings were found to align. There was a difference of 0.75 inch in line and 0.25 inch in grade. The remarkable speed at which this accurate work was carried along shows that the undertaking was attended by clever supervision and excellent engineering skill throughout.

LETTERS TO THE EDITOR.

Fixed Carbon Limitation.

Sir,—In connection with the articles on the desirability of introducing a fixed carbon determination into specifications for the purchase of asphalt, I have only to add that, based on an experience of 25 years in the determination of this and other characteristics of the native bitumens, I believe it to be of the utmost value in several directions, and I may say that in the hands of a person of experience and enjoying daily practice in conducting the operation, there is no difficulty in obtaining results which are reliable within any error which is of importance.

The value of the determination of fixed carbon in any bitumen, and I should preferably denominate its residual coke, ash free, as involving less uncertainty as to the nature of this material, depends upon the direction in which it is applied and the manner in which the results are interpreted. Determinations of fixed carbon aid in differentiating bitumens of various characteristics or origin, and the requirement for such a determination in any specification may mean that under such specification bitumen of only a certain character is desired. If an engineer, in the light of service tests, prefers material which has been well proved to be satisfactory rather than residual pitch which has been a failure or is of an experimental nature, he will properly introduce into his specifications a provision that no bitumen would be acceptable under them which contains more than 15% of fixed carbon. In this direction a requirement of this nature is of the greatest value. On the other hand if he desires to purchase the cheaper and more experimental forms of bitumen, there would be no object in such a provision. In another direction, as Mr. Pullar has shown, the determination of fixed carbon in bitumens, representing any particular class of materials is most important in determining their uniformity, and the fact that they have not been overheated in the process of manufacture.

The value of the fixed carbon test, therefore, may be said to be based upon the care with which it is carried out, the objects for which it is used. and the intelligence with which the results are interpreted. We are certainly very much indebted to Messrs. Kirschbraun and Pullar for the efforts that they have made to show in what directions this determination is important and how it is to be interpreted.

If a city desires to use some of the cheaper and carelessly prepared residuals to the exclusion of the more expensive natural asphalts, there would be little object in introducing a fixed carbon clause in the specification, but if the highest grade of material is desired to the exclusion of the cheaper residual pitches made from oils which are unstable at the high temperatures used in their production, such a clause should certainly be one of those which should be provided.

CLIFFORD RICHARDSON.

New York, N.Y., Dec. 11th, 1913.

[NOTE—See issues of *The Canadian Engineer* for Nov. 13th, Nov. 20th, Nov. 27, Dec. 4th and Dec 11th for previous articles and discussions concerning the value of the "Fixed Carbon Test" in specifications for asphalt. This is an important subject for Canadian city engineers to consider, and the opinions which have already been expressed in these columns respecting the limitation of the percentage, being those of well-known engineering

chemists who have given the subject a careful study, differ to a degree warranting thorough discussion.—Editor.]

Discussion on "Stresses in Circular Pipes."

Sir,—The bending moments in Circular pipes due to an uneven distribution of the internal pressure, the subject of Mr. Hogg's very interesting and timely paper, have been persistently ignored by many alleged experts to the detriment of the structure.

In reading over Mr. Hogg's paper, it appeared to the writer that, besides those formulæ Mr. Hogg has given for the bending moments due to a vertical load distributed over the horizontal section of the pipe and to a horizontal pressure uniformly distributed over a vertical section, it might be useful to give formulæ for the case

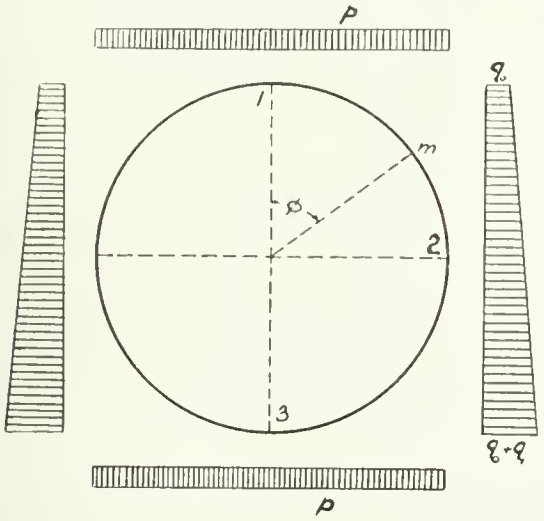

Fig. 1.

when the horizontal pressure is unevenly distributed, as shown in the accompanying diagram.

A circular structure is, generally speaking, three times statically indeterminate, but on account of the vertical diameter in this case being an axis of symmetry for the load, there will be no transversal force at the top of the pipe; by choosing the stresses at the top as the statically undeterminate quantities, it will be seen that there are only two in this case, the horizontal force and the bending moment.

By proceeding in the usual manner it will be found that the bending moment and normal force at the top (point 1) is

$$M_1 = \tfrac{1}{4} r^2 (p - q - 5/12\ q)$$
$$N_1 = -(q_0 + 5/16\ q) r$$

p being the vertical load per unit length, q_0 and $q_0 + q_1$, the horizontal load per unit length at the top and bottom respectively (see Fig. 1) and r the radius. The bending moment is taken positive when it produces compression on the convex side of the pipe and the normal force positive for tension.

At the end of the horizontal diameter (point 2) the forces are

$$M_2 = -\tfrac{1}{4} r^2 (p - q_0 - 6/12\ q_1)$$
$$N_2 = -pr.$$

and at the bottom (point 3)

$$M_3 = \tfrac{1}{4} r^2 (p - q_0 - 7/12\ q_1)$$
$$N_3 = -(q_0 + 11/16\ q_1) r$$

The bending moment and normal force at the various point in (see diagram) can readily be determined from the values of the statically indeterminate quantities which (acting from the centre of the circle on the top section) are for this loading case

$$\text{(Normal force) } X_n = r (q_0 + 5/16\ q_1)$$
$$\text{(Moment) } X_m = -\tfrac{1}{4} r^2 (p + {}^1 q_0 + 5/16\ q_1)$$

and the bending moment M_m and the normal force N_m at the point which has the co-ordinates X and y.

$$M_m = M_{01m} - X_m - X_n y$$
$$N_m = N_{01m} - X_n \cos \phi$$

where M_{01m} and N_{01m} are the corresponding values in the statically determinate auxiliary system.

V. J. ELMONT.

Montreal, Dec. 9th, 1913.

The Binnie Contract.

Sir,—The engineering papers are taking considerable interest in the Ottawa pure water scheme, and particularly in the terms of contract which the city of Ottawa has made with Sir Alexander Binnie, who, after proposing the scheme, has been retained as its designing and supervising engineer. A New York engineering paper, which has always taken a sympathetic interest in Canadian engineering matters, apart from the size of the fee, appears to be struck with the peculiar nature of the contract. It points out that he is to substitute his own staff and force for the ordinary city department, which usually has control of the construction of a new waterworks for its own city. It calls this "an extraordinary contract," and decidedly unique "in a civilized, modern city the size of Ottawa." The contract is certainly both unique and extraordinary. One would expect to see such a contract, as the journal suggested, in those out-of-the-way countries where local authority is not sufficient to undertake the establishment of its own engineering force.

It certainly does seem ridiculous, if not manifestly unjust, to pay Sir Alexander Binnie a percentage on the costs of his own services; for, in this contract a sum of $1,000,000 (to be exact, $976,320) has been included for "engineering and contingencies," on which amount Sir Alexander Binnie gets $50,000, or 5 per cent. Again, there is the sum of $500,000 for land damages, and on this amount Sir Alexander is to receive $25,000. One would imagine the lawyers as best entitled to receive this latter sum. What engineering features there exist in the purchasing of right-of-way, and of the lands to be flooded, is difficult to discern, being little more, at any rate, than the survey of the outlines of these lands. Here, then, is a sum of $75,000, which is to be paid Sir Alexander Binnie, but to which, manifestly, he has no right, either by reason or engineering ethics.

By all means let Sir Alexander Binnie be paid his 5 per cent. on the cost of the construction of the Ottawa pure water scheme, estimated, apart from land damages and engineering, at $6,500,000, the percentage allowance of which would be $325,000, a fairly good fee as engineering pay goes; but there is no logical reason, ethically or morally, and least of all from a business point of view, in paying him $75,000 on a percentage basis for "engineering and contingencies" and for "land damages."

The total cost of the new system will be $8,000,000, on which Engineer Binnie, at the rate of 5 per cent. of

this cost, gets $400,000. The items of cost are approximately:—

$5,500,000 for gravity flow steel pipe line.
500,000 for land, compensation, etc.
1,000,000 for engineering and contingencies.
1,000,000 for cost of construction.

In the first item, which is also the chief item, the cost of design and supervision is comparatively small. In the second item the engineers have little or no work to do. The third comprises the cost, not of any part in the construction of the water scheme, but the time and skill of the engineer. The fourth item is wholly constructional, but of a kind that does not involve any excessive amount of high-class engineering work. Evidently, there is room for criticism and objection on the most practicat ground.

In justice to the city of Ottawa, it should be stated that if there was one thing more than another that decided the City Council in favor of placing the whole responsibility for the construction of the Gatineau Lake project on the shoulders of the eminent engineer who recommended the scheme, it was, undoubtedly, the disastrous experience which the city had had with its new intake pipe and aqueduct. "Once bitten, twice shy." This probably accounts for the almost perfect unanimity of the citizens with the agreement, in the face of the most extraordinary conditions, as above set forth, in the provisions of the contract.

Ottawa people have the greatest confidence in the Mayor, and heartily congratulate themselves on having at the head of their municipal administration, a man so capable of grappling with any new situation as it comes up. But Mayor Ellis is not an engineer, and, however faithful and honest his intentions, he is scarcely capable of judging the merits of this agreement submitted by Sir Alexander Binnie.

The proper course to be taken by the Mayor and Council, would be to consult some capable engineer, not necessarily "eminent" or "knighted," of which there are men residing in Ottawa, or at any rate, in other Canadian cities, before agreeing to the Binnie contract, and binding the people of Ottawa to pay out to an engineer the large sum of $75,000 to which he is in no way entitled.

Yours truly,

J. A. MACDONALD.

Ottawa, December 4th, 1913.

PAVEMENT REQUIREMENTS IN OTTAWA

A REPORT ON THE COST OF PUTTING INTO GOOD CONDITION ALL THE STREETS OF THAT CITY—RECOMMENDATIONS INCLUDE TEN TYPES—BRIEF DESCRIPTION OF EACH PAVEMENT

PURSUANT to instructions from the City Council of Ottawa to prepare a report on the estimated cost of placing all the thoroughfares within the city in good condition, Mr. Arch. Currie, the city engineer, has presented to the Board of Control the following summary (Table I.) of the lengths, areas and costs of the various classes of roadways it is recommended should be constructed:—

TABLE I.

		Miles.	Length, lin. ft.	Area, sq. yds.	Cost.
1.	Asphalt	9.81	51,814	183,263	$ 502,297.50
2.	Asphalt macadam	15.24	80,495	260,308	558,370.00
3.	Asphalt and stone blocks	5.53	29,205	140,672	472,955.00
4.	Asphalt macadam stone blocks	1.20	6,340	36,320	96,068.40
5.	Concrete	1.09	5,770	23,520	39,420.00
6.	Macadam tar painted	47.01	248,214	783,013	1,300,266.80
7.	Macadam tar painted and stone blocks	.42	740	2,460	5,072.50
8.	Macadam tar painted and granitoid	.75	3,970	13,055	23,755.75
9.	Stone blocks	.87	3,560	15,338	66,782.00
10.	Tar macadam	2.87	15,150	52,912	107,121.60
		84.32	445,258	1,511,361	$3,172,119.55

In deciding on the various classes of roadways proposed to be constructed, very careful consideration had to be given to the amount and nature of the traffic on any particular road, with a certain assumption of what it might be in the future.

The following descriptions of each type of roadway will be of some interest.

Asphalt.—As there is nearly 40 miles of asphalt pavement in Ottawa at present, very little need be said about it, but some alterations are required in the specifications, such as altering the proportions of the mixtures, etc. It is proposed to construct asphalt pavement on streets with very heavy traffic, such as will be found near railway freight yards and on streets where street cars are running, except in the track allowance and 18 inches on either side, which should be paved with stone blocks or setts. It has to be understood that asphalt pavement should not be used on grades steeper than 5 per cent. The advantages of this pavement are:—

(*a*) Ease of traction.
(*b*) Comparative noiselessness under traffic.
(*c*) Imperviousness to water.
(*d*) Ease of cleaning.
(*e*) Pleasing appearance to the eye.
(*f*) Suitability to all classes of traffic.
(*g*) No vibration or concussion in travelling over it.

The defects are:—

(*a*) Slipperiness under certain conditions of the atmosphere.

(*b*) Disintegration if excessively sprinkled or otherwise subjected to constant moisture (although asphaltum is impervious and insoluble in either fresh or salt water).

(*c*) Tendencies to become soft under traffic in extreme heat and to present a wavy surface, and under extreme cold it may crack and become friable.

(*d*) Unsuitability for steep grades.

Asphalt Macadam.—It is proposed to use this form of construction on streets where the traffic is not quite so heavy as would be on asphalt pavement, and with the same foundation course, viz., concrete. It takes the place of sheet asphalt on grades steeper than 5 per cent.

The most common type of asphalt macadam roadway is laid on a Telford base, this base consisting of stones about 8 inches thick, laid on edge. The course on top of the concrete base, or the Telford base, whichever is decided upon, is composed of stone from 1¼ inches to ⅜ of an inch, mixed with bitumen in its melted condition. From 17 to 20 gallons of bitumen will be used to each cubic yard of stone, thus covering completely each particle.*

This mixture is then laid on the concrete to a depth, after rolling, of not less than 3 inches. Before rolling, a grit course of clean stone screenings is spread over the surface in such quantity as will cover and fill the voids in the surface. The excess of this grit course is then removed and the road swept clean, and over the surface a squeegee coat of bitumen is applied, using about ½ gallon per square yard. Over this again is spread the excess of screenings which was previously removed, to correct the stickiness of the bitumen. The road is then well rolled, until the screenings are bonded with the bitumen of the squeegee coat.

Asphalt and Stone Blocks.—This refers to work on streets where street cars are running. Asphalt has already been dealt with, while, as formerly stated, it is considered necessary to have stone blocks for the full width of the track allowance, and 18 inches outside on both sides. Several of the streets at present have sheet asphalt or some other bituminous mixture in the track allowance with, in some cases, only one or two courses of blocks outside. This, it is contended, is poor construction, as with the continued vibration of the rails, the sheet asphalt soon becomes disintegrated and crumbles to pieces, causing holes adjoining the rails and consequent danger to vehicular traffic. While stone blocks are not perfect, owing to surface drainage difficulties, they are preferable to asphalt, and failures in the blocks can be easily and rapidly repaired.

Another form of construction in the track allowance is solid concrete. This has been used with considerable success in Montreal.

Asphalt Macadam and Stone Blocks.—This is practically the same form of construction as described for asphalt macadam and asphalt with stone blocks, it, of course, being understood that sheet asphalt macadam is introduced for vehicular traffic on a grade with a concrete base for heavy traffic and, as already described, with a Telford base for traffic of a somewhat lighter nature.

Concrete.—Concrete for roads is somewhat of a modern idea, but so far seems to have been very successful and with proper care, particularly in drainage, there is no apparent reason why construction of this nature should not be successful. It will be necessary to reinforce this concrete and also provide transverse expansion joints about 50 feet apart. The surface of the road might well be painted with some bituminous mixture, and afterwards sprinkled with sand, all tending to give a good surface.

Macadam Tar Painted.—This type of roadway will be built on the principles laid down by that well-known Scotchman, Thomas London Macadam, and not by some of the modernized versions of them. It is considered that many of the residential streets in the city, where traffic is light, should be macadamized. Where a foundation course is necessary a Telford base, as already described, should be put in. However, in numerous cases in the city it is not necessary to build a foundation course, some streets having had a good stone foundation course for years, in which cases all that is required is that this old foundation course be trimmed off to the proper convexity, then stone to pass through a 2-inch ring be laid to a depth of 5 inches. It should be then thoroughly blinded with gravel and a little clay, watered and thoroughly rolled. This is admittedly a cheap form of construction and suitable for light traffic in residential districts, and it is submitted that this form of construction is most suitable for a very large number of streets in the city of Ottawa.

The control and prevention of dust on this class of road is one which should have very serious and careful consideration, and particularly in view of the automobile traffic which in all likelihood will develop. Dust has always been a feature of macadam roads, being at the same time the result of use and a check upon excessive wear. Prior to the introduction of automobiles, dust was considered as nothing more or less than a nuisance; to-day, however, the existence of macadam roads depends upon the retention of the road dust formed by the wearing of the surface. It has been found from experience that the broad pneumatic tires of heavy automobiles driven at high speeds draw out by suction the small particles which bind the material of a macadamized road, with the result that the road soon disintegrates.

Various methods are in use for preventing or reducing dust, amongst which might be mentioned sprinkling with fresh or salt water, a mixture of water and calcium chloride, oil emulsion, and impregnating or surfacing with crude oils or coal tar products. The writer has tried all these methods and has come to the conclusion that good tar, properly applied, is the cheapest and best dust preventative and preservative of macadam roads, being both effective and durable. The quality of the tar is very important. If it is heated too much, and refined to too great a degree, it becomes brittle and makes black dust. If not sufficiently refined, and the light oils taken off, it will disintegrate.

Before tarring a road surface the weather should be warm, to be favorable; and the road thoroughly brushed and cleaned. The tar should be heated to its boiling point at convenient positions on the works, and should be applied as hot as possible, so that it may flow freely. Immediately on application the liquid tar should be brushed in so far as necessary to ensure regularity in the thickness of the coating.

The quantity of tar required will vary according to the physical conditions of the road, but generally, in the case of a road to be treated with tar for the first time, the quantity should be one gallon to coat from 5 to 7 superficial yards.

*The mixing will be done at the city's asphalt plant.

If the road must be opened for traffic before the tar has set hard, grit should be spread on the surface to prevent the tar from adhering to the wheels of the vehicles, but gritting should be dispensed with as long as possible, and the quantity of gritting material to be spread should be no more than sufficient to prevent the tar from adhering to the wheels. Stone chippings, crushed gravel, coarse sand, or other approved material (free from dust) not larger than will pass through a ¼-inch square mesh should be used for gritting, in quantity not exceeding 1 ton for 300 or 350 superficial yards, if grit is used, and 1 ton for 200 superficial yards if coarse sand is used.

Precautions should be taken to prevent liquid tar passing directly through drainage gratings or outlets.

For the safety of the public, precautions should be taken by lighting, watching and warning.

The question of tarring has been dwelt upon at considerable length, but it is one which is all-important, not only as a dust preventative, but in increasing the life of the road.

Macadam Tar Painted and Stone Blocks.—This construction is intended for residential districts in which street cars are running and ordinary vehicular traffic is light. Both forms of construction have already been described.

Macadam Tar Painted and Granitoid.—This is another form of construction for residential districts in which street cars are running. Granitoid is really a concrete roadway with a specially finished surface. The concrete above the foundation course is laid with a very strong mixture of cement with a ¾-inch top laid with cement and granite or marble screenings, the latter being absolutely free from dust. Particular attention has to be paid to the sub-drainage of the concrete, otherwise there is sure to be trouble and subsequent failure of the work.

This form of construction has been tried successfully in Montreal, Westmount and Maisonneuve.

Stone Blocks.—It is considered that stone blocks should be used on streets traversed by extra heavy traffic. The stone for block paving should be specially selected and tested, the requirements being a tough stone which at the same time will not become unduly slippery under horse traffic.

The difficulty with stone block, or, in fact, with any block paving, is the laying and jointing. The usual custom is to lay the blocks on a cushion of sand, but the opinion is expressed that this is more of a detriment to this type of paving than otherwise. If moisture could be kept out it would be useful, but as soon as the moisture gets in, the sand starts to run, leaving the blocks suspended in one place and heaved up in another. All this trouble can be greatly overcome by laying and jointing these blocks with a cement grout, but most important of all is ample subdrainage.

Tar Macadam.—Tar macadam is a comparatively new road material. As a material for footways it has long been used in different forms. In some of the northern towns of England it has been used for roads for some years past, but its increasing employment is mainly due to the development of the motor and cycle traffic, and to the attempts that are being made to cope with the "dust problem." Its superiority over ordinary macadam is generally acknowledged. Some of its advantages, in this respect, may be summed up as follows:—

(1) It is more unperishable. The metal being coated and partly permeated with a viscous coating of tar, the stone does not absorb water. The surface coat is finer than ordinary macadam, and has fewer voids in it, so that water does not penetrate so easily.

(2) It has a longer life. The tarry coating, besides preserving the stone from the influence of the weather, largely nullifies the attrition accruing in ordinary macadams, and the tar is a better binder than any of those employed. In general, the road is more homogeneous and elastic.

(3) It is practically noiseless.

(4) It preserves a smoother surface than ordinary macadam. The dust is reduced to a minimum so that the cost of scavenging and watering is practically avoided.

(5) The coat of maintenance as regards repairs is less.

Its disadvantage is that of a slightly greater initial cost, but this is compensated for by its longer life. One engineer has complained that the surface is apt to be slippery in frosty weather and others have urged that the surface will become soft and sticky under hot sun. In most cases it is mentioned as suitable for "light traffic," or traffic "not too heavy." From this it might be erroneously inferred that tar macadam is inferior to ordinary macadam as regards wear. Tar macadam will take heavier traffic than ordinary macadam, but that it can be substituted for the necessary pavements in the streets of large towns and cities is too much to suppose. Its chief purpose will be to supersede ordinary macadam in small country towns and villages, main country roads, and suburban and residential quarters of the larger towns and cities.

Stone.—The stone most recommended for tar macadam is limestone, but iron slag has been found equally good and is of greater strength. Many satisfactory roads have been made with a mixture of limestone and slag. Some of the igneous rocks have been tried, but as a rule, these are too compact for crystalline to absorb any appreciable proportion of the tar, which, therefore, remains as a surface coating that easily wears off. A few engineers have, however, employed igneous stone and have been satisfied with the results; so that the question is still open. Derbyshire dolomitized limestone, Kentish rag, and Scarborough grit stone, have been largely employed for tar macadam. Mr. Purnell Hooley, who has long studied and experimented with this material, is an advocate of iron slag, and he is the patentee of a specially prepared brand of tar macadam. The question of adding coke-breeze or other fine material to the topping coat is one in dispute. At Harrogate 12% of coke-breeze is invariably added, and the borough engineer finds the topping coat improved thereby.

Tar.—The tar requires very careful watching. As previously mentioned, the surface of tar macadam has in some instances become exceedingly sticky and troublesome in hot weather; in some cases so much so that pedestrians' boots have stuck to the road and had to be left there. This is due to (*a*) the stone used not being suitable; (*b*) the material not being properly prepared, and, (*c*) the tar being defective.

In nine cases out of ten, defects in tar macadam may be attributed to the tar. The tar produced by different works varies exceeding in quality. The most recent tar-extracting apparatus employed in gas works does not appear to produce such good tar as formerly, and the brand of coal used also has a bearing on the subject. Unfortunately, the difference between poor and good tar cannot at present be established by analysis; samples of both

appearing chemically the same. The advice given by one well-known engineer is to find a gas works producing good tar, and use only the tar produced there.

The tar macadam is laid on the roadway in three grades, over a good foundation, which is always shaped up to the proper convexity. The aggregate of the surface is composed of broken stone, obtained in the vicinity: 60% broken to a size of 2½ in.; about 30%, 2½ in. to 1¼ in.; and 10%, ¾ in. to ½ in., for closing up interstices. The last-mentioned size is kept separate and used during rolling operations. The tar macadam, after being spread and levelled, is rolled into a smooth surface but not rolled to the same extent as an ordinary water-bound macadam road. A 10-ton roller is used for this work, as better results are obtained than when a heavy roller is used. After the roadway has been open for several weeks, a coating of tar is applied to the surface of the road, and covered with stone chippings, not larger than will pass through a quarter-inch mesh.

Engineers differ considerably about the preparation of materials, and no standardization is at present possible. Heating the stone dries it, and renders it in a better condition to absorb tar. On the other hand, it is contended that artificial drying is detrimental, and also that it is better to dry the stone by storage under cover. It is doubtful whether the latter method can be effectual for, though the stone is preserved from actual wetting, it will, in wet and humid weather, absorb moisture from the air.

As to the necessity of boiling the tar, there should be little doubt. Tar varies very much in the amount of volatile matter present and careful boiling for 2 or 3 hours will render the consistency more stable and more tenacious. If the tar is poor a little pitch may be added to enrich it. The boiling, however, must never be carried too far or the residue will be brittle. Considerable care must be exercised with the boiling. In preference to boiling, some engineers store their tar for some months before use, and in this case it is kept in concrete or iron tanks, set below the ground level, and fitted with valves, etc., to permit the escape of volatile gas. The tar should, in this case, be drawn from the bottom of the tank, and a pump must, therefore, be fitted to effect removal under this condition.

General.—The estimate of $3,172,119.55 would appear at first sight to be an enormous expenditure, but a study of the details and close examination of the streets in the city will convince anyone of the vast amount of work that has to be done and it has to be remembered that good roads cannot be constructed without a heavy expenditure of money.

The opinion is expressed that the first work to be undertaken is the construction of roadways which form the main arteries or trunk roads in the city.

The report is concluded by a paragraph pointing out that proper maintenance is as important as good construction, but that it cannot reasonably be expected that the small amount of about $50,000 given annually for the maintenance of roads in Ottawa is anything like sufficient.

Maintenance consists in keeping a roadway as nearly as practicable in the same condition as it was when originally made. The repair of a roadway is the work rendered necessary to bring it up to its original condition after it has become deteriorated by neglect to maintain it. There is a wide distinction between the two operations; the former keeps the road always in good condition, while the latter makes it so only occasionally.

ELECTRIC IRON SMELTING.

By Jens Orten-Boving, M.I.Mech.E., London, England.

THE method of producing iron and steel by the use of electric current has lately received much and well-deserved attention in Canada. It may, therefore, be of some interest to learn some data regarding the recent experiences and developments in Sweden. Before doing so, the fact might be pointed out that there is no other country in the old world so like Canada as Sweden. Both are mainly agricultural countries with a relatively sparse population; both have an abundance of water power, forest and high-class iron ore; both have splendid transport facilities, i.e., rail, lake or canal, and the climate is marked by similar fluctuations of temperature and by the remarkably clear, invigorating atmospheric conditions.

During the last five years some very remarkable developments in the iron industry of Sweden have taken place by the introduction of electric reduction of iron ore, producing pig iron, and by electric refining of low-quality steel to high-grade steel.

This article will deal with the two processes separately, although in many plants the refining should be an integral link in converting the ore into fine steel by one continuous process.

Electric Reduction of Iron Ore.—The system which has met with real commercial success is that of Electro-Metals, Limited, which has been described on several occasions in various technical papers. Other methods have been tried repeatedly but they have all been abandoned and to-day the Electro-Metal furnaces are the only ones in use in Sweden. The following is a list of Swedish furnaces:—

Working now.	Number.	Power consumed per furnace.	Total power consumed.
Strömsnäs Jernwerks A. B.	1	3,000	3,000
Uddeholm A. B. Hagfors ..	3	3,400	10,200
Stora Kopparbergs Bergslag A. B. Domnarfvet.....	1	3,600	3,600
Building now.			
Strömsnäs Jernwerks A. B.	1	3,000	3,000
Nykroppa Jernwerk	2	3,400	6,800
	8		26,000 h.p.

These furnaces will produce approximately 80,000 tons of pig iron per annum. The Stora Kopparberg Co. are putting down 10 more furnaces, not included in the above.

There are, further, a great many installations contemplated and it is certain that wherever there is cheap water power the old blast furnaces will be replaced by electric producers. Generally speaking, it holds good that wherever one horse-power per annum can be produced cheaper than the cost of two tons of charcoal or coke (depending on what class of iron is to be produced) it is a commercially successful undertaking to substitute electric heat for carbon heat.

The operation of the electric reduction furnace is much simpler than that of a blast furnace and everybody who has been visiting the Swedish works returns impressed by the extreme simplicity of the affair. Fewer hands are required as well as less skill than for a blast

furnace. The prime costs for the electric plant are also lower.

The following tables give all the data required for calculating the cost of one ton of iron produced. For a plant of, say, three furnaces of each 3,000 h.p. capacity the following staff and labor would be required: 1 chief engineer, 1 assistant, 2 chemists, 3 foremen, 2 electricians, 10 men in each of 3 shifts.

Table I.

Continuous Run of One Furnace Belonging to Strömsnäs Jernwerks A. B. from Oct. 1, 1912, to Sept. 1, 1913.

Number of charges	26,549
Weight of ore used, tons	11,338
Weight of limestone, tons	907
Weight of charcoal, tons	2,700
Produced pig iron, tons	7,258.3
Weight of charcoal used per ton of pig iron, lbs.	830
Total number of hours when running normal, hours	7,957
Total power consumed kw. hour, kw. hour	15,291
Total power consumed per ton iron, kw. hour	2,107
Weight of pig iron produced per 1 horse-power year, tons	3.05
Weight of pig iron produced per 1 horse-power year, tons	4.14
Total consumption of electrodes, tons	28.42
Consumption of electrodes per ton of pig iron produced, lbs.	8.7

operation, in August No. 2 was running, and now No. 3 is ready for starting up.

"The plant was originally designed for two furnaces only of 3,000 h.p. capacity each (the power consumption is actually 3,400 h.p.). The furnaces are placed in the central bay; on one side all the electrical gear is placed, transformers, switches, regulators, etc., this part being entirely isolated from the metallurgical part. The power is generated 9½ miles away at Forshufvud which power station belongs to the company. The voltage is 12,000 on the line and is reduced to low pressure by the transformers and adjusted by the regulators to between 50 and 100 volts as required.

"The furnaces, as well as the whole of the plant, have been designed by the Electro-Metals Co. and are mainly following the lines of the well-known Trollhattan furnaces, although the various details naturally show modifications based upon the experience from Trollhattan. There are 6 electrodes, cylindrical in shape and arranged to be used continuously without waste by screwing the ends together.

"The pouring bay is conveniently fitted with an electric overhead traveller as well as trolley tracks for transporting iron and slag. The iron can either be poured to pig or conveyed in ladles to the Bessemer and open-hearth works. The slag is run into block moulds and makes excellent building stone.

"The crushing room is at the end of the furnace building. There are 3 crushers of the ordinary jaw type. There is a railway track outside and the daily requirements are supplied in the trucks so that there is no need

Table II.

Continuous Run of the Trollhattan Furnace for Three Three-month Periods from 1st October, 1912, to 30th June, 1913.

(This furnace was run by the Swedish Association of Iron Masters with a view to establishing the practical success of the system as well as to give the various members an opportunity of trying their various kinds of ore. Thus, in the table below different kinds of ore were used during the period indicated.)

Period.		1 Oct., 1912, to 31 Dec., 1912.	1 Jan., 1913, to 31 March, 1913.	1 April, 1913, to 30 June, 1913.
Number of charges		6,193	7,107	7,281
Kiruna A ore	Tons	1,047	223.3	799.8
Tvollavara ore	"	973.4	123.3	762.6
Klacka-Lerberg ore	"	885.6	1,453	1,426.5
Persberg ore	"	8.82	47.97	148.4
Total ore	"	2,914.8	3,047.6	3,137.4
Limestone	"	169.94	252.8	273.5
Charcoal	"	699	719	738
Pig iron produced	"	1,905.86	1,933.32	2,000.14
Charcoal per ton pig iron	Lbs.	825	835	830
Actual Working time	Hours	2,158.5	2,113.7	2,147
Consumed power kw. hours	Units	3,957,565	4,095,588	4,216,544
Consumed power per ton pig iron	"	2,076	2,118	2,108
Produced pig iron per kw. year	Tons	4.22	4.14	4.15
Produced pig iron per h.p. year	"	3.10	3.04	3.05
Consumption of electrodes, total	"	5.307	8.670	7.896
Consumption of electrodes per ton pig iron	Lbs.	6.2	10.0	8.8

Note—The ore from Kiruna and Tvollavara is of the highest quality obtainable in Sweden. It will be seen that the output of the furnace as well as the consumption of electrodes depends largely on the quality of the ore used.

At a meeting at Kristinehamn of the iron masters in the district last spring the following observations were made by the chief engineer of the Hagfors electric furnace plant after the first year's running:

"The work with the foundations of our plant was commenced at the middle of April, 1911; eleven months later, or the 15th of March, 1912, furnace No. 1 was in

for big storing bins. One of the crushers is fairly large with wide enough jaw space for the biggest lumps, and the ore passes from the crusher to the smaller ones, and thence by a bucket elevator up to a belt conveyer above the charging platform so that the raw material may be unloaded where required. There is a small ore store but this only contains some limited reserve amounts of the

various kinds of ores used. These are from Taberg, Finnmossen and Nordmark. The charcoal is transported from the stores by a ropeway.

"Up to now three different kinds of pig iron have been produced: (1) Pig iron for open-hearth treatment; (2) pig iron for Lancashire treatment; (3) pig iron for Bessemer treatment.

"The quality which is desired for the open-hearth pig is semi-spiegel and contains Si, 0.40-0.60%; Mn, 0.30-0.50%; P., 0.011-0.018%; S., 0.015%.

"It will be seen later on that it is more economical to produce pure spiegel iron in the electric furnace, and arrangements are being made to alter the open-hearth furnaces so as to use spiegel iron only.

"It has been assumed in various quarters that it would probably be difficult to maintain a constant product in an electric furnace. Experience shows, on the contrary, that a much more constant product is obtained from the electric furnace than from our old blast furnaces. One of the reasons for this fact is that there is such a large receiver or collecting basin in the lower part of the electric furnace that this collector acts as a regulator on the quality.

"The Lancashire pig needed is quite white and has the following analysis: Si, 0.20-0.30%; Mn, 0.20-0.30%; P., 0.011-018%; S., 0.015-0.020%.

"In the beginning there was a tendency for the sulphur to be unduly high but this was put right by making the slag more basic whenever the furnace was run for Lancashire pig.

Bessemer Pig.—"The analysis of the quality used is: Si, 1.00-1.40%; Mn, 2.50-3.00%; P., 0.015-0.019%; S., 0.005%.

"Excellent Bessemer has repeatedly been made of this pig. At first the result was not good, but it was soon found that we had to increase Si and Mn. It had been assumed that the amount ought to be as usual, but the reason for the higher content being required is probably that the temperature of the electro-Bessemer pig is lower than for ordinary Bessemer pig from blast furnaces.

"We intend, however, to re-arrange the receiver in our electric furnace with a view to increase the temperature. Our general experience points to the following results: It is cheaper to make spiegel than grey pig because: (1) More current can be put through the furnace; (2) the current consumption is lower; (3) thus the production is higher; (4) the electrode consumption is lower; (5) the repair costs are lower.

"It may further be stated that rich charges give better results than poorer. The quality of the pig is not influenced by the percentage of iron contents of the ore.

"The electrode consumption has been relatively high and this is influenced by the following conditions:—

"1. High power consumption (which, of course, increases if the charges are poor).

"2. Too lively gas circulation and too large a proportion of CO_2 in the gas. (Of course the carbon consumption is correspondingly lower).

"3. Too large electrodes for the load.

"Since the 15th of January we have used the gas from the furnaces as fuel under our open-hearth furnaces and I estimate the value of the gas at from 2 to 3 shillings per ton of pig iron produced.

"Finally, regarding the influence of the electric pig on the finished steel, our experience shows that the change tends to make better steel; this holds good both for Bessemer as well as soft and hard open-hearth steel."

The steel produced at Hagfors is of the highest quality and is mainly used for locomotive boiler tubes, piano wires and high-tension wires generally. Practically the whole of the output is exported.

In Sweden generally the electric reduction of iron ore is regarded as revolutionizing in this industry and elaborate preparations are being made for constructing mills of considerable capacity. Recent experiences have shown that larger electrodes can be used at the same time as the current intensity on the electrodes is increased. Larger furnaces will therefore be designed and some of those now projected will have a capacity 8,000 h.p. each.

It has been found that when using coke instead of charcoal it is advantageous to run on burnt lime, as otherwise the power consumption is too high, which largely depends on too much CO_2 being produced.

Refining Furnace.—The Electro-Metals refining furnace is designed for 2-phase current, although 3-phase may be used by suitable design of the transformers and coupling the connections on Scott's system. The furnace has been correctly and carefully described in the July 25th, 1913, number of the *Electrical Review*, as well as in the *Iron and Coal Trades Review* and various other publications. A number of these furnaces are now in operation in Sweden and in Sheffield, England, and the working results are highly satisfactory.

To run this type of refining furnace is extremely simple, everything being so well arranged and balanced that any steel melter who knows open-hearth work can take charge of the electric furnace. No special training or skill is required from an electrical point of view.

These furnaces give a marvellous product inasmuch as it is quite easy to produce a high-class steel from any ordinary scrap with the greatest ease. The ordinary steel smelter used to open-hearth work will not believe the results in the beginning, but once he has familiarized himself with the proper use of various slags to remove sulphur and phosphorus, as well as how to determine the carbon content or to add alloys, he will be loath to return to the open-hearth furnace which, indeed, is a very clumsy and incomplete apparatus compared with the electric refining furnace.

The process is equally suitable for high and low grade steel, for castings, drills, tool and quality steel of every kind and use.

In a country like Canada, where electric current may be produced cheaply from water power the resmelting and refining of ordinary cheap scrap in an electric furnace becomes a very attractive undertaking, and it is curious that it has not been started long ago.

The following figures, taken from an article published in the *Electrical Review* of July 25th, give the actual costs of production.

Working Costs.	Per ton steel £	s.	d.
Electrode consumption	0	4	0
Lining, roof, felting	0	6	0
Slag materials	0	2	6
Labor (assuming auto-regulation)	0	6	0
Tools	0	1	0
Electric energy, 825 kw. hours @ .6d.	2	1	3
	3	0	9

These are actual figures taken from the Works cost sheets and are obtained from a furnace of 2½ tons capacity, so, naturally the figures are considerably reduced in larger furnaces.

It should also be noted that a very high rate is paid for the electric energy, as this is obtained from the municipal supply and is generated by steam. In Canada, utilizing water power, the current could easily be supplied at 0.2d. per kw.hr. corresponding to a charge of £6 per horse-power year based on 300 days a year continuous full load; consequently, in using the above figures as a base to figure out cost of production in Canada it must be borne in mind that although the cost of labor would be undoubtedly higher, the cost of electric energy would be only one-third and the total cost, as shown by the above figures, would be in the neighborhood of £2 os. od. per ton.

If a new iron works were planned in Canada electric reducing and refining should be used throughout and it is certain that with judicious arrangements adapted to the special requirements of the country such an undertaking would pay handsomely and the quality obtained would be so high that it would exclude the importation of a good many standard products of iron and steel.

Anybody interested in these matters need only look up the government's statistics on import to compile a very long list of raw material and half finished goods which could and should be made in the country.

THE OXIDATION OF COAL AND OF THE PROCESS OF COMBUSTION.*

By Horace C. Porter.

IT is well known from the work of several investigators in European laboratories and from earlier work at the Bureau of Mines that all coals unite with oxygen more or less at ordinary temperatures. The action is at ordinary temperatures largely a simple addition, very little gaseous products of combustion being produced. There is, however, a development of heat by the simple addition of oxygen, and this heat development is the primary cause of spontaneous combustion.

As the temperature rises, the oxidation reactions increase rapidly in rate, and the simple-addition reaction becomes complicated with the development of water and oxides of carbon as products of the oxidation and with the production of water and of methane and other gases by destructive distillation.

Under whatever conditions coal burns, as for example on the fuel bed of a boiler furnace or in suspension as dust in the air of a mine, the earlier stages of oxidation proceeding at the lower temperatures have important bearing on the ease of ignition of the fuel and the degree of inflammability of its dust. In order to throw more light on the nature of the combustion reactions at successive stages and to determine how the various kinds of coal differ in their rates of reaction with oxygen, a laboratory study has been made of the oxidation of coal, at temperatures ranging from 80 deg. to 300 deg. C.

A series of experiments has been run with samples of different coals placed in atmospheres of pure oxygen at a pressure reduced so as to equal the average partial pressure of the oxygen in air. The rate of absorption of oxygen by the coal was determined by admitting pure oxygen at such a rate as to maintain constant pressure in the apparatus. Large differences in rate were found between different kinds of coal, and the comparative oxidation rates thus found conform in general to the known comparative degrees of inflammability of these coals.

At temperatures above 200 deg. C. the production of CO_2 and other gases causes a considerable error in an experimental method which does not remove these gases as they are formed. A rapid-stream method was, therefore, devised in which weighed samples of dry coal were heated at definite temperatures in a rapid stream of dry air for one hour, the change in weight of the coal being accurately determined as well as the amounts of H_2O, CO_2 and CO produced. From these data the total oxygen used and the oxygen fixed were calculated.

It was shown that the oxidation of coal consists in the earlier stages of the formation of an unknown complex of the coal substance with oxygen, and the more or less gradual dissociation of this complex as the temperature rises into water, CO_2 and CO. Below 200 deg. water is the chief product of this dissociation, the proportion of CO_2 in the products increasing as the temperature rises. Carbon monoxide is a primary product of the oxidation of coal at temperatures between 100 deg. and 300 deg. C. and possibly also outside of this range. Triangular diagrams representing the relationship of the three products H_2O, CO_2 and CO at different temperatures show interesting tendencies, e.g., toward constancy in ratio between CO_2 and CO within a certain temperature range.

The production of water by oxidation of coal at 100 deg. C. or lower is of interest in connection with the devising of methods for accurate moisture determination in coal. The direct production of CO at moderate temperatures is of interest in connection with mining operations and the storage of coal.

*An address delivered at the annual meeting of the American Chemical Society, Rochester, N.Y., Sept. 9-12, published by permission of the Director of the Bureau of Mines.

Returns made to the Bureau of Mines show that the metal output of Ontario for the first quarter of 1913 was as shown in the accompanying table:—

Product.	Unit.	Quantity.
Gold	Oz.	50,637
Silver	Oz.	7,264,559
Copper	Tons.	3,075
Nickel	Tons.	6,311
Iron ore	Tons.	15,389
Pig iron	Tons.	181,042
Cobalt and nickel oxides	Lb.	280,096

The principal gold producers are the Hollinger and Dome; but the McEnany and MacIntyre also contributed, as well as the Cordova in Hastings County, and the Canadian Exploration Company at Long Lake. The Foster-Tough mine at the new camp of Kirkland Lake is turning out some rich ore. The quantity of ore milled in all was 69,905 tons, the average yield of gold being thus a little under ¾ oz. per ton. The production of silver was nearly equal to that for the corresponding period of last year, being only some 74,485 oz. less. The mines of Cobalt proper furnished 7,253,595 oz.; South Lorrain, 198,381 oz.; Gowganda, 54,350 oz., and from gold bullion, 10,964 oz. Shipments amounted to 7,053 tons ore, 2,130 tons concentrates, and 1,926,160 oz. of bullion. Silver refineries in Ontario recovered 2,754,292 ounces. The Sudbury mines yielded 1,589 tons more of nickel and 538 tons more of copper than during the first three months of 1912. The producing companies are the Canadian Copper Company and the Mond Nickel Company, but a third company, which acquired the holdings of the Dominion Nickel-Copper Company, is actively preparing for production.

EXPERIMENT AT SHERBROOKE, QUE.

Professor Barnes, of McGill University, and Lieutenant Daw, a post-graduate student of the same institution, have studied the flood question at Sherbrooke, Que., and believe that a proposed scientific experiment will prove a solution to the problem. Every spring the country at Sherbrooke is flooded by the anchor ice in the rivers, which causes the pack ice to form and, thereby, holds back the water, which spreads over the low lying country to its great detriment.

Lieutenant Daw has been given permission from his commanding officer, Lieutenant-Colonel Harrison, of Montreal, to form a field corps of Canadian engineers. The matter has been submitted to head authorities by Colonel Harrison, and Lieutenant Daw has been informed that the authorization of his scheme is expected to be in orders within two months.

The services of forty-two engineers will be utilized, in conjunction with those of Professor Barnes, to relieve Sherbrooke from its annual floods. The scheme is that at a crucial moment, when the anchor ice is about to accumulate the pack, this troop will be summoned by alarm bombs from the armory to assemble post haste and proceed by motor, oar, or horse to the scene of danger, either in the night or day time. Arriving at the anchor ice field, they will drill the ice in a scientific manner, place gun cotton primers in the holes, attach electrical connection carrying leads to a safe point of observation, and after receiving the trumpet calls from up and down the river, on both sides, to the effect that the inhabitants within range of the explosion are out of danger, and have opened their windows to prevent them being broken by the dynamic and static shocks of the explosion, the mine will be fired.

Lieutenant Daw has received a request from the town of Richmond asking him to organize a corps on similar lines for that town's benefit; and also letters from the Minister of the Interior informing him that he is so interested in the matter that he has laid the scheme before the Ministers of Public Works and Militia.

If the scheme is successful, and those who advocate it are very confident that it will be, it may also be tried on the St. Lawrence River to prevent the floods on the South Shore, which also take place in the spring every year, through somewhat similar causes.

ARCH BRIDGE AT SASKATOON.

Though the contractors—the R. J. Lecky Company, of Regina—were delayed in getting their outfit on the ground, good progress has been made on the construction of the arch bridge over the Saskatchewan River from the intersection of 25th Street and Spadina Crescent on the west bank to the intersection of Clarence and Saskatchewan Streets on the east bank. The work was commenced on September 2nd, and already the excavation for five piers has been completed; and one pier, one retaining wall, and one pedestal, have been finished. Boring tests have been put down in all the excavations with a view to determining the nature of the foundation and all were found highly satisfactory.

Throughout the winter months, a force of 80 men will continue building operations; but in the spring this number will be greatly augmented. And by December 1, 1914, Saskatoon is to have an arch bridge unsurpassed by any like structure in Canada, being the largest reinforced concrete bridge in this country, and taking high rank among the great bridges of the North American continent. Its approximate cost is $400,000; and under the terms of the agreement entered into between the city and provincial government, the former is to pay one-third and the latter two-thirds of the cost of the structure.

The plans prepared through the instructions and under the direction of the highways commissioners, call for a bridge consisting of a series of arches with a floor on practically a 3 per cent. grade from east to west, in order to meet the rise on the university side of the river. The total width of the structure is to be 65 feet. Two 8-foot sidewalks are to be cantilevered from the roadway, while provision is made for two street car tracks and two 14-foot roadways, making ample room for each section.

The arches of 150 feet are notable as being longer in span than any in the Dominion of Canada. The total length of the bridge and the retaining walls at its approaches is to be about 1,490 feet. It consists of one arch of 25 feet span, one arch of 66 feet span, one arch of 92 feet span, one arch of 103 feet span, one arch of 136 feet span, four arches of 150 feet span, and one irregular arch of 94 feet span.

Special care was used in working out the design and the allowable stresses are considered most moderate. The variations of temperature cause the concrete to expand or contract, the bridge being designed for a temperature range from 50 degrees below Zero to 90 degrees above. In all probability this variation of temperature is larger than that contemplated for any other concrete bridge ever built.

The site selected presented various engineering difficulties. Chief among these was the elevation of the east side bank about fifty feet higher than on the west bank. During high water the river is 1,100 feet wide at this point. Special care also had to be exercised from an aesthetic standpoint, for the bridge will cross from a park on the east side to the University grounds on the opposite side of the river.

A new company has been formed to connect North and South Shields, Eng., by tunnel, through which an electric railway will run. A quarter million pounds sterling has been assured and the sanction of Parliament for the project is to be asked at the next session. At present communication across the mouth of the Tyne is by ferry only, and the service is frequently interrrupted by stormy weather. Liverpool and Birkenhead were successfully linked by tunnel some years ago.

A concrete hardening material now being introduced contains 95 per cent. iron dust or iron flour, which is mixed with cement for finishing the surface of concrete floors, says "Engineering News." From 15 to 25 lbs. of the material is mixed with 100 lbs. of the cement while dry, and one part of this mixture to two parts of sand makes the slush for the top coat, which varies from ½ to 1 in. in thickness. It is said to make a hard and durable floor, which is waterproof and not slippery. The hardening material is used also to make new concrete adhere to old concrete in repair work. This concrete hardener is made by the Globe Steel Company, of Mansfield, Ohio.

COAST TO COAST.

Mawer, Sask.—The steel of the Grand Trunk Pacific has now reached Mawer, a town staked out but three months ago, but now having a population of 450 people.

Calgary, Alta.—Two new street car lines have been put into operation at Calgary—e.g., the extensions to Bankview and Glengarry, in the south district, and to Capitol Hill on the north.

Guelph, Ont.—At the November meeting of the Light and Heat Commission, Manager Heeg reported that there had been 323 electric services and 10 power services installed during the past year, as well as 338 gas services. In addition to these, 37 electric street lights have been installed.

St. Marys, Ont.—At a meeting of the water, light and heat board, Superintendent Miller stated that from January 1st to October 31st the board had a net profit from the electric light department of $650. The waterworks department showed a deficit.

Montreal, Que.—The C.P.R., G.T.R., and C.N.R., all reported an increase in weekly earnings for the first week in December of this year over the corresponding week of 1912. The increase for the C.P.R. was $238,000; for the G.T.R., $10,102; and for the C.N.R., $15,100.

Brandon, Man.—The report on the street railway for the month of November shows that the returns for that month average $7.46 daily in excess of the month of October, although the cost of operating is practically the same, and although the number of miles operated is approximately 2,000 less.

Fredericton, N.B.—The inauguration ceremony in connection with the commencement of the operation of a regular train service on the new Gibson and Minto Railway was conducted by Sir Thomas Tait; while that in connection with the Southampton line was carried out under Manager Sherwood's management.

Vancouver, B.C.—Owing to the high price at whi .. water frontage and suitable sites for shipyards are held on the mainland and points on Vancouver Island, it has been stated with authority that it is improbable that the famous Yarrows Shipbuilding Company, of Scotland, will locate a site for a plant in British Columbia.

Vancouver, B.C.—A statement that the appropriation of $5,000,000 for Vancouver's harbor development includes the cost of the $4,000,000 government dock, has been contradicted. Neither is the cost of dredging False Creek included in the appropriation. The dock and dredging are being done under the supervision of the department of public works.

Calgary, Alta.—The surplus of the city of Calgary's municipal electric light department for ten months amounts to $40,000, according to figures that have just been compiled. The city buys power en bloc from a company which develops it at a hydro-electric plant on the Bow river, and also generates a greater quantity itself by means of a steam plant.

Peterborough, Ont.—The erection of the ornamental iron standards in connection with the Hydro-Electric street lighting system on Hunter and Simcoe Streets is progressing, and when these have been erected and the lamps placed, the downtown lighting system as originally proposed and outlined by Mr. Jeffery, engineer for the Hydro-Electric Commission of Ontario, will be complete.

Berlin, Ont.—Extensions to the Berlin waterworks system, costing $100,000, are practically completed. Water from nine artesian wells will be pumped by Hydro power instead of by steam plant. The new concrete stand pipe in North Ward, the largest on the continent, and the immense reservoir at the pumping station were filled some days ago, and will provide high pressure in case of fire.

Kaslo, B.C.—The arrival of the first locomotive at Kaslo over the new standard gauge railway line from Whitewater was celebrated by a smoking concert, attended by the municipal officials, prominent members of the board of trade, and citizens. Credit for the prompt completion of the line was given to W. P. Tierney, the Vancouver contractor, and to E. A. Sharpe, the C.P.R. engineer.

Montreal, Que.—According to the recent statement of J. McMillan, general superintendent of western lines, nearly 6,000 miles of wire and new lines have been constructed by the C.P.R.'s telegraph in the west this season. More exactly the figures are: 3,240 miles of copper wire, 1,420 miles of iron wire, 689 miles of railway equipped with train telephone despatching circuit, and 475 miles of telegraph along new railway and extension work still in progress, making a grand total of 5,824 miles of wire.

Montreal, Que.—The work on the western section of the Grand Trunk Pacific is being carried on in British Columbia, from Rose Lake to Hutton—217 miles; in Sasktachewan, the Prince Albert branch—36 miles,—the Moose Jaw Northwest branch—19 miles,—the Weyburn branch, 20 miles; in Manitoba, the Brandon branch—26 miles. This means that in a few months this line will be a continuous unit; and the company has ordered additional equipment so as to commence an efficient and standard service.

Nelson, B.C.—The receipts of the Nelson Street Railway show a gratifying increase of $107.40 for the month of November, 1913, over the corresponding month of last year and an increase during the first week of December of $55.25 over the same period of last year. For the month of November the receipts amounted to $1,200.45, while for November, 1912, they amounted to $1,003.25. The first week of December the earnings of the company were $368.00, and for the corresponding week last year the earnings amounted to $312.75.

Montreal, Que.—The Calgary Power Company, for the 11 months ending November 30th, showed satisfactory increases over the corresponding period last year. For 1912 the gross earnings were $178,486; for 1913, $213,672. For 1912 the net earnings were $145,583; for 1913, $171,318. The fourth unit at Bow Falls is now practically completed and everything will be ready to commence generating power from this additional unit early in December. By the installation of the fourth unit the capacity of this plant is increased to 19,000 h.p.

Ottawa, Ont.—An increase in traffic on Canadian canals amounting to more than four million tons for the navigation season of 1913, which officially closed on November 30th, over the total tonnage of traffic recorded for the corresponding period of 1912 is shown in the report issued by A. W. Campbell, Deputy Minister of Railways and Canals. The total tonnage through Canadian canals for the past navigation season was 51,319,426 tons. Last year the total was 46,952,605 tons. The figures for the 1913 year, therefore, show an increase of 4,366,821 tons.

St. John, N.B.—The Quebec Railway Company, which has recently filed its petition before the State Railway Commissioners at Augusta for permission to construct 111 miles of track from Washburn westward to the Canadian boundary line of Maine, will, according to President Arthur Gould, ultimately form a continuous electric line between the tidewater at St. John and Quebec. The Canadian Pacific and the Aroostook Valley roads would combine with the new line to form the continuous chain between the two cities. The section of the road between Andover, N.B., and Washburn has already been built and is in operation.

Victoria, B.C. Premier McBride has stated, in connection with President Wilson's recent message to Congress in

the United States concerning railway development in the north, that he believes the construction of a line of railway north and south through British Columbia providing access to the Atlin and the Yukon to be a national enterprise. He says that closely linked with such a possibility as the establishment of this line is the building of railways in Alaska and the eventual linking up of that district with the United States proper by means of steel running through the Yukon and province of British Columbia.

Fredericton, N.B.—Up to the month of December 72 miles of rails had been laid on the St. John Valley Railway, according to the report presented to the Provincial Government at the closing meeting of the December sessions. The estimates for work on the Valley Railway during the month of November amounted to about $100,000, while progress reports showed $142,000 of work done in October. Of the steel now laid, 25 miles is south of Fredericton and about an equal distance north and also south of Woodstock. Construction work will be carried along as much as practicable throughout the winter.

Toronto, Ont.—The construction of a new double circuit power line between Niagara Falls and the main transmission station at Dundas, the doubling of the present line between Dundas and St. Thomas by way of London, and the enlargement of half-a-dozen sub-stations, all to cope with the rapid expansion to the consumption of power, have been practically decided upon by the Ontario Hydro-Electric Commission. The construction of the Niagara Falls-Dundas line will necessitate the acquisition of a right-of-way and involve an expenditure of approximately half a million dollars; and the doubling of the Dundas-St. Thomas transmission line will mean another hundred thousand.

Ottawa, Ont.—It has been stated by Controller Nelson, of Ottawa, that this year over 5 miles of pavements have been laid at a total cost of $300,000, 13 miles of sidewalks at a cost of $70,000, and sidewalk repairs to the extent of practically two miles of new walks. However, Alderman McNeill has taken an active interest in traffic regulations this year, and states that next year Ottawa will have to devote more money and attention to roads. He claims that the money now allowed for maintenance is insufficient. There has been much repair needed which could not be undertaken this year, and holes in roadways should be repaired at once, not when they have become a menace to traffic.

Victoria, B.C.—Mr. Taylor, minister of public works, is reported as having declared that within the next year or two British Columbia will possess an up-to-date highway, extending from Kamloops to Tete Jaune Cache, and giving connection through to Edmonton. The provincial government has already established a good road for about 90 miles north of Kamloops along the north Thompson river, and it is to be extended later north to Tete Jaune Cache, where it will meet the highway built by the Grank Trunk Pacific contractors, east and west. It is probable that this road will be taken over by the province from Tete Jaune Cache to the provincial boundary line at Yellowhead pass; and already a fairly good railway contractors' road extends through the Rockies to the east along the Grand Trunk Pacific route to Edmonton.

Vancouver, B.C.—Ever since the new Coquitlam dam of the B.C.E.R. company was completed several months ago, water has been rising rapidly; and not long since poured for the first time over the spillway, proving the company's scheme to provide an adequate water supply for its power houses at Lake Buntzen to be a success. The water takes a drop of 73 feet from the top of the spillway to the bed of the river below. There is now stored behind the dam 8,000,000,000 cubic feet of water, or 50,000,000,000 imperial gallons. From Coquitlam Lake, as now enlarged, water is drawn off by means of the tunnel to the two power houses on the shore of the north arm of Burrard Inlet. The capacity of the spillway is three times the maximum flood into the lake and the dam has been constructed so that water will never pour over it.

Ottawa, Ont.—The proposed route of the All-Red Railway and Steamship Line, which is to seek incorporation at the next session of parliament, is from Cape St. Charles, on the coast of Labrador, north of Newfoundland, through northern Quebec to Winnipeg, and on to Dean Inlet, on the Pacific coast, running north, but parallel with the G.T.P., where it turns south to the coast. This route will reduce the time, it is claimed, between Winnipeg and Liverpool to four days. The route between the Atlantic coast and Winnipeg is through virgin country, which contains immense quantities of pulp. It is proposed to connect with the C.N.R. at Quebec. The time between New York and Liverpool by rail to Cape St. Charles, thence by steamer, will be reduced to three days and two nights. Owing to the shortening of the ocean trip it is thought very much traffic could be diverted from New York. As the road will follow the height of land, very little bridge building will be required.

Victoria, B.C.—The 50 arc light set and a spare transformer for the city light station are expected to arrive daily in the city, having been shipped from Peterboro. An installation of the lights on Ross Bay seawall driveway will be completed this month, the conduits having been put in when the street was paved some months ago. The "Park" type of fixed lights will be utilized, the light being attached to the standard, this rigid variety being considered the best, owing to the exposed position of Ross Bay. When this work is completed, the only portion of the waterfront from the city boundary to the outer wharf, unlit at night, will be the stretch of macadam across Beacon Hill Park. In order to rearrange the lodes for arc lighting, trunk connections are being installed through the city from Herald Street eastwards, and when the cables are in, the lode on circuits in the east and south-east portion of the city will be re-distributed. A number of new lights are being installed, and with the payment for the new equipment now on order, the loan of 1911 will about be used. City Electrician Hutchison believes that the future arc lighting extensions can be cared for out of revenue after the loan is expended.

Victoria, B.C.—Eight new bridges are now being constructed by the provincial board of works department, and three bridges are being renewed. Work on all of the structures is to be completed early next spring. Most important among those under construction is the bridge at Taghun, near Nelson, B.C., which will span the Kootenay river, and will cost about $90,000. It will comprise 3 steel spans with approaches, and will rest on steel cylinder piers filled with concrete. The bridge to be constructed across the North Thompson river at the mouth of the Barrier river, 40 miles north of Kamloops, will comprise one swing span and two fixed spans. Three bridges are being constructed across the Eagle river between Sicamous and Revelstoke; and two are being built over the Skeena river, one at Terrace, and the other at Smithers, this latter to have piled piers and Howe truss spans. The last of the eight new bridges is Clayton's bridge, to be built over the Bella Coola river. Those being renewed are one at Princeton, which will be a wooden truss structure on concrete piers, and will span the Tulameen river; one across the Okanagan river at Penticton, a swing-span bridge; and the third over Toby creek at Athalmar, in the Columbia district. Nothing definite has been done yet in connection with proceedings on the actual construction of the proposed Pit river bridge on the Dewdney trunk road.

Vancouver, B.C.—As far as the money available will allow, it is likely that the city will go ahead with the building of the causeway across Coal Harbor, and that the Park Board will move back the zoo and gradually improve the

surroundings of the harbor immediately. The work of building the causeway will be for the city works department, $155,000 having been appropriated for the preliminary expenses of the project. Ald. S. J. Crowe, chairman of the Civic Board of Works, declared recently that he was in favor of calling for tenders for the causeway immediately so that the city could go ahead with the work first thing in the spring, or as soon as money was available. Plans were passed some time ago by the Civic Bridges and Railways Committee, and they are said to have been drawn up with a view to conforming to the Mawson scheme. Chairman W. R. Owen, of the Park Board, said that the Board had asked for the approval of only the ground plan drawn up by Mr. T. H. Mawson, and that the work to be done, while gradual in effect, would conform to the general plan. In the meantime, the Park Board, he said, would trim up Coal Harbor and as soon as possible begin to fill in round the edges until the circular lake was formed. There was no intention in the plan of doing a great deal of expensive embankment work at once, but grassy slopes would likely be the scheme at first.

Montreal, Que.—Early in the morning of December 10th, at a point some 620 feet below the highest point of Mount Royal, the two headings of the Canadian Northern tunnel met almost exactly fifteen months after the first heading in the tunnel was commenced, and on the same day the first train ran through the tunnel from the west portal to the Dorchester Street shaft. Though the two heads started over three miles away from one another, when they were joined the grades were practically the same. Guests invited to make the first journey through the tunnel included Chief Justice Sir Charles Davidson, Acting Mayor Drummond, Controller Dupuis, Mr. Cowie, chief engineer of the Harbor Commission, J. E. Dalrymple, vice-persident of the Grand Trunk Railway, David McNicoll, vice-president of the C.P.R., Mr. Fairbairn, chief engineer of the C.P.R., Mr. Safford, chief engineer of the Grand Trunk Railway, Phelps Johnson, managing director of the Dominion Bridge Company, Prof. McLeod, secretary of the Canadian Society of Civil Engineers, G. H. Duggan, vice-president of the Dominion Bridge Company, and Professors Adams, Porter and Bancroft, of McGill University. This establishes a new record for deep tunnelling on the American continent and takes the record from the United States, while, with the exception of certain of the Swiss tunnels, where the headings are much smaller and the rocks softer, the achievement of the Canadian Northern engineers is a world's record.

PERSONAL.

W. D. L. HARVIE and M. A. REID have been elected public utilities commissioners for Lethbridge. ALEX. GRACE received the appointment of public works commissioner.

A. D. SMITH, for some time manager of the Western Electric Company at Fort William, Ont., has been appointed electrical inspector for that city, to assume duties January 1st.

J. K. SKAMMELL, District Engineer for the Department of Public Works at Fredericton, N.B., has been obliged to discontinue his services for the time being owing to severe accidental injury sustained recently

HON. ADAM BECK, Chairman of the Hydro-Electric Power Commission of Ontario, who was in New York last week in an advisory capacity respecting the feasibility of power development, sailed for England on the 13th instant.

T. H. HOGG, B.A.Sc., has been appointed to succeed Mr. C. H. Mitchell, C.E., as one of the representatives of the graduate body of the Faculty of Applied Science on the Senate of the University of Toronto, Mr. Mitchell having recently resigned.

TH. SEIDL, Manager and Chief Engineer of Messrs. Escher, Wyss & Company, Montreal, started on a short trip to Switzerland on the 16th December. Mr. Seidl expects to be back in Montreal on 20th January. During his absence Mr. Withers will be in charge of the office.

ARTHUR H. BLANCHARD, M. Can. Soc. C.E., professor in charge of the graduate course in highway engineering at Columbia University, on December 6th delivered an illustrated lecture on "Modern Developments in Highway Engineering" before the Drexel Institute of Philadelphia.

J. T. BRECKON, hydraulic engineer, Vancouver, has been recommended to take charge of Vancouver waterworks system under Mr. F. L. Fellowes, Supervising City Engineer. Mr. Breckon is a native of Oakville, Ont. He has had twenty-five years' experience in Canada and the United States in connection with waterworks, power plants, water supply and sewage disposal systems. Since September, 1912, he has been in charge of the design and construction of the waterworks system for the Associated Cement Company at Bamberton, B.C.

BACK COPIES WANTED.

One of our subscribers, anxious to bind his copies of *The Canadian Engineer*, is minus the following issues: Feb. 19th, 1909; May 4th, 1911; May 11th, 1911; May 18th, 1911; May 25th, 1911; June 1st, 1911, and would be glad to pay 25 cents per copy for any of them. Will subscribers who happen to have these numbers, and who do not care to keep them, kindly send them in to this office, and we will see to it that they are put into the hands of the party interested?

MANITOBA BRANCH CANADIAN SOCIETY OF CIVIL ENGINEERS.

At the annual meeting of the Canadian Society of Civil Engineers, held in Winnipeg on the 4th instant, Professor E. Brydone-Jack was elected chairman for the ensuing year, with Mr. G. E. Bell as Secretary-Treasurer. It will be remembered that Professor Brydone-Jack was secretary last year, while Mr. J. G. LeGrand was chairman. The new secretary may be communicated with at Box 2918, Winnipeg.

It is reported that on Dec. 2nd a mechanical section of the Canadian Society of Civil Engineers, Manitoba Branch, was organized. Mr. A. C. Frith was chosen chairman of this section; Mr. R. R. Neild, vice-chairman, and Mr. J. F. Tracey, secretary. The executive committee consists of Messrs. J. W. Dorsey, S. S. Kennedy, T. L. Roberts, W. J. Gilmore, W. Jardine, and R. Milne. The next meeting of the section will be held on the first Monday in January.

COMING MEETINGS.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS.—Seventh Annual Convention will be held at Great Northern Hotel, Chicago, December 29th to 31st. Secretary, I. W. Dickerson, Urbana, Ill.

MINING AND METALLURGICAL SOCIETY OF AMERICA.—Annual Meeting will be held in New York City, January 13th, 1914. Secretary, W. R. Ingalls, 505 Pearl Street, New York.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20939—December 2—Amending Order No. 10568, February 26th, 1910, to provide that crossing of Plymouth Road be protected by day and night watchmen; cost of maintaining gates be apportioned: 15 per cent. by town of Welland, 10 per cent. by Tp. Crowland, and remainder by M.C.R.R. Co.

20940—December 3—Approving location C.P.R. Swift Current North Westerly Branch from point in Sec. 16-23-20, W. 3 M., at mileage 111.17, to point in Sec. 12-5-3, W. 4 M., at mileage 134.38, and authorizing construction of said branch across 23 highways.

20941—December 5—Approving location C.P.R. Bassano Easterly Branch Line from point on East Boundary of N.E. ¼ Sec. 13-24-1, W. 4 M., at mileage 118.39 to point in Sec. 6-26-21, W. 3 M., at mileage 180.20. And authorizing construction of said line across 63 highways.

20942—December 1—Extending until July 1st, 1914, time for approval of C.P.R. tolls between points in Canada west of and including Sudbury, Ont., to and from points west of Sudbury, from, and to points east thereof, and east of and including Windsor, Ont., also included in said tariff; during such period C.P.R. is allowed to charge tolls it was authorized to charge under Acts 7-8, Edw. VII., Chapter 61.

20943—December 2—Authorizing, temporarily, until June 1st, 1914, C.L. and W. to operate trains over crossing of Oshawa Electric Ry., at mileage 158.85, at Prospect St., town of Oshawa, Ont., subject to condition that crossing be protected by flagman appointed and maintained by and at expense of Ry. Co.

20944—December 3—Approving location C.P.R. station at Willon, S.E. ¼ Sec. 10-14-28, W. P. M., Man., at mileage 26.5, on Virden-McAuley Branch.

20945—December 2—Authorizing C.P.R. to construct spur on parcel of land leased from Government, lying northeasterly of right-of-way of C.P.R. main line, and Dog Lake, in Tp. 46, Dist. Algoma, Ont., at mileage 58.8, Lake Superior Division.

20946—December 1—Extending, until July 1st, 1914, time limited by Sec. 4, Ch. 61, of Acts 7-8 Ed. VII., and extended until December 1st, 1913, by Order No. 19423, dated May 30th, 1913, for approval of G.N.W. Tel. Co.'s tolls between points in Canada west of North Bay, also to and from points west of North Bay and to points east thereof, and east of and including Windsor, Ont., also included in said tariff, during such period G.N.W. is allowed to charge tolls it was authorized to charge under Acts 7-8, Ed. VII., Ch. 61.

20947—December 1—Extending, until July 1st, 1914, time for approval of Can. Nor. Tel. Co.'s tolls for the transmission of telegraph messages between points in Canada; during such period C.N. Tel. Co. is allowed to charge tolls it was authorized to charge under Acts 7-8 Ed. VII., Ch. 61.

20948—December 3—Authorizing Can. Nor. Western Ry. Co. to construct across and connect with tracks of City Industrial Spurs in city of Medicine Hat, Alberta.

20949—December 2—Authorizing C.N.R. to construct spur for the Scott Fruit Co., city of Regina, Saskatchewan.

20950—December 1—Extending, until July 1st, 1914, time for approval of White Pass and Yukon Route tolls for transmission of telegraph messages between points in Canada; during such period company is allowed to charge tolls it was authorized to charge under Acts 7-8, Ed. VII., Chapter 61.

20951—December 1—Extending, until July 1st, 1914, time for approval of G.T.P. Tel. Co.'s tolls for transmission of telegraph messages between points in Canada, with exception of tolls of Co. between its local offices, on its Ottawa Division, in Provinces of Ontario and Quebec, and between them and Swanton, Vt., approved by Order No. 11153, dated July 12th, 1910; during such period Tel. Co. is allowed to charge tolls it was authorized to charge under Acts 7-8, Ed. VII., Chapter 61.

20952—December 4—Authorizing G.T.P. Ry. to construct Government Road Diversion across main line in S.W. ¼ Sec. 35-52-1, W. 5 M., at mileage 818-6 west of Winnipeg, Dist. North Alta., Alta.

20953—December 5—Authorizing C.P.R. to construct siding at Melba, across highway between N.W. ¼ Sec. 18-17-3, W. 3 M., and N.E. ¼ Sec. 13-17-4, W. 3 M., at mileage 41.9 from Moose Jaw, Sask.

20954—December 5—Relieving C.P.R. from providing further protection at crossing of First Avenue, village of Souris, Man., at mileage 16.6 on Estevan Subdivision, ¼ mile west of Souris Station.

20955—November 24—Directing that crossing at Broadway Street, town of Yorkton, Sask., be protected by a watchman, appointed by C.P.R., from 8.30 a.m. to 8 p.m., except during grain shipping season, when such crossing be protected night and day; wages of watchman be borne 60 per cent. by Ry. Co., and 40 per cent. by town of Yorkton.

20956—December 5—Extending, until May 15th, 1914, time within which C.P.R. complete spur for Canadian Metal Shelter Company, Winnipeg, Man., authorized under Order No. 19325.

20957—December 5—Authorizing C.P.R. to construct, by means of grade crossings, an additional track (double track) of main line, Sask. Division, Swift Current Subdivision, across five highways—M. 40. 8, N.W. ¼ Sec., 17-17-3, W. 3 M.; 2. M. 43 7, Sec. 23 and 26-17-4, W. 3 M.; 50.3, Secs. 25 and 26-17-5, W. 3 M.; 4. 51.3, Secs. 26 and 27-17-5, W. 3 M.; and 5, mileage 66.69, Secs. 22 and 21-17-7, W. 3 M., Ernfold, Sask.

20958—December 5—Amending Order No. 20502, by striking out figures "15" wherever they occur in recital and operative parts of Order and inserting in their place and stead figures "14," so as to make Order read, "and across Sec. 27, Tp. 18, R. 14, W. 2 M."

20959—December 5—Authorizing C.P.R. to use and operate Bridge No. 613 on Teeswater Subdivision, Ont. Division.

20960—December 3—Authorizing G.T.P. Branch Lines Company, to construct spur for Hamilton Brothers, village of Fort Qu'Appelle, Sask.

20961—December 4—Approving plan "B," dated November 25th, 1913, filed by G.T.R., and showing location of transfer track, town of Port Hope, Ont.

20962—December 3—Directing that, within 60 days from date of this Order, G.T.R., install automatic electric bell at crossing of highway, between Cons. 6 and 7, Tp. Otonabee, ½ mile west of Keane Station, Ont., 20 per cent. cost of installing bell paid out of Ry. Grade Crossing Fund, remainder by Ry. Company.

20963—December 5—Authorizing G.T.P. Branch Lines Company to operate trains over crossing of C.N.R., Maryfield Branch in N.W. ¼, Sec. 9-5-6, W. 2 M., Dist. Assiniboia, Sask., without their being brought to a stop.

20964—December 4—Directing that G.T.R., within 60 days from date of this Order, install improved type of automatic bell at crossing of public road west of Ste. Justine Station, Que.; 20 per cent. of cost of installing said bell be paid out of Railway Grade Crossing Fund, remainder by Ry. Company.

20965—December 4—Extending, for a period of 1 year from December 1st, 1913, Order No. 12723, dated December 6th, 1910, subject to condition that crossing be protected by gates, to be erected and operated by and at expense of applicant company (C.N.O.R.).

20966—December 9—Substituing plan No. 53515 as revised to December 5th, 1913, for plans approved under Order No. 20827, dated November 14th, 1913. 2. Openings be left in said bridge between piers 11 and 12 and piers 15 and 16, as shown on plan marked Plan "A."

20967—December 10—Approving proposed Supplement No. 2 to Canadian Freight Classification No. 16, as finally revised and submitted for approval by G. C. Ransom, Chairman, Can. Freight Association, by his letter dated Montreal, December 6th, 1913, effective not later than January 20th, 1913.

20968—December 6—Authorizing G.T.P. Ry. to construct highway between Secs. 32 and 33-51-20, W. 4 M., Alta., across its main line at mileage 763.7, west of Winnipeg.

20969—December 5—Approving revised location G.T.P. Ry. main line from East Line of Lot 5337 to West Line of Lot 5336, Cariboo District, B.C. Also approving location of station in Lot 5336, mileage 95, Yellowhead Pass West, B.C.

20970—December 6—Authorizing C.P.R. to reconstruct Bridge No. 2.0, Montreal Terminals, Eastern Division.

20971—December 10—Amending Order No. 20775, dated November 6th, 1913, by striking out figure "8" after words "Lot No.," in seventh line of operative part of Order, and substituting therefore figure "5."

20972—October 31—Establishing collection and delivery limits of Express Companies in Edmonton, Alta.: And rescinding Orders Nos. 14987 and 15759, dated respectively 11th September, 1911., and 8th January, 1912.

20973—December 4—Establishing collection and delivery limits of Express Companies in city of Levis, Que.

20974—December 9—Authorizing city of Edmonton, Alta., to operate its Electric Street Ry., over G.T.P. Ry., at 27th Street, pending installation of half-interlocking plant required to be installed under Order No. 20793, subject to and upon conditions that crossing be protected by flagmen, appointed and maintained by and at expense of city; cars of city be stopped 100 feet from diamond; trains of G.T.P. Ry. to approach crossing under control, prepared to stop if electric railway is making crossing.

20975—December 9—Extending, until April 1st, 1914, time within which G.T.R. install gates at crossing of Wallace Avenue, Toronto, Ont.

20976—December 9—Authorizing Edmonton, Dunvegan and B.C. Ry. to construct bridge across Athabasca River, mileage 131, west of Edmonton, Alta.

20977—December 9—Authorizing. Esquimalt and Nanaimo Ry. to consruct across Campbell Street, Nanaimo, to serve Nanaimo Pressed Brick and Terra Cotta Company.

20978—November 27—Authorizing C.L.O. and W. Ry. (C.P.R.) to operate trains, temporarily, until June 1st, 1914, over crossing of Toronto and Eastern Ry., at junction of Scugog and Wellington Streets, town of Bowmanville, mileage 149.2 from Glen Tay.

20979—December 9—Authorizing C.P.R. to construct spur for Imperial Oil Co., Limited, Montreal, Que.

20980—December 3—Approving and authorizing clearances as shown on plan of C.P.R. siding for Imperial Oil Company, Calgary, Alta., subject to condition that men keep off sides of cars while operating said siding.

20981—December 9—Extending, until April 1st, 1914, time within which G.T.R. commence construction of subway at crossing of Thompson Rd., Tp. Bertie, and directing work be completed within 4 months from that date; pending completion of subway, G.T.R. employ day and night watchmen at said crossing; wages of watchmen be paid—15 per cent. by P.M.R.R. Co., 30 per cent. by M.C.R.R., 47½ per cent. by G.T.R. and 7½ per cent. by Tp. Bertie. Rescinding Order No. 20921, dated November 20th, 1913.

20982—December 6—Authorizing G.T.R. to construct siding into premises of Frontenac Wall and Tile Company, part Lot 5, Con. west of Great Cataraqui River, Tp. Kingston, Co. Frontenac, Ont.

20983—December 9—Directing C.N.R. to dig a ditch 3 feet wide by 3 feet deep, from west end of British America Elevator, to connect with old ditch at east switch, to bridge just east of road allowance, Engelfeld, Sask. Ry. Co. grade driveway and aproaches to elevator and loading platform along south side of station grounds, and grade team-track driveway for distance of 300 feet from west side of Engelfeld Milling Company's building, work to be done by August 1st, 1914.

20984—December 10—Amending Order No. 20905, November 25th, 1913, by substituting words "tracks of the G.T.P. Branch Lines Company," for words "G.T.P. Railway," where they occur in Order.

20985—December 9—Authorizing C.P.R. to open for traffic its Virden McAuley Branch from mileage 13.5 to 36.0, Man.: Provided speed of trains be limited to rate not exceeding 20 miles an hour.

20986—December 10—Approving location C.N.O.R. station grounds at Coniston, Tp. Neelon, District Nipissing, Ont., at mileage 257 from Toronto.

20987—December 10—Approving location C.P.R. station at Broadacres, Sask., on S.W. ¼, Sec. 32-35-21, W. 3 M.; and rescinding Order No. 18915, dated April 14th, 1913, in so far as it approves location of station in Sec. 6-37-21, W. 3 M.

20988—December 10—Establishing collection and delivery limits of Express Companies in town of New Liskeard, Ont.

20989—December 9—Authorizing C.P.R. to construct proposed wye at Tregarva, Sask. Division, Colonsay Subdivision, across Railway Avenue Lane in Block 2 and Gregg Avenue, Tregarva, Sask.

20990—December 9—Authorizing C.P.R. to reconstruct Bridge No. 49.8 over Salmon River, Orford Subdivision, Eastern Division, near Kingsbury, Que.

20991—December 9—Authorizing C.P.R. to construct, at grade, Kootenay Central Ry., across four (4) highways in Lots 5033 and 4596 (Provincial Government Survey), East Kootenay District, B.C.

20992—December 10—Authorizing city of Fort William, Ont., to cross, at level, with its double track line of Street Ry., on Frederica Street, the tracks of G.T.P. Ry., where same cross Frederica Street, city of Fort William. Question of apportionment of cost of installation and maintenance of half-interlocking plant is reserved.

20993—December 9—Directing that C.N.R. divert road allowance from a point north of Ry., to farm crossing, thence to road allowance in Sec. 12-19-24, Man. Mun. provide necessary right-of-way upon payment by Ry. Co. of $200.

20994—December 9—Authorizing G.T.R. to construct spur across Montreal Street and the Port Arthur and Fort William Electric Street Ry., at West Fort William, Ont., for Canadian Car and Foundry Co., Limited.

20995—December 9—Approving plan showing details of superstructure of C.L.O. and W. Ry. (C.P.R.) bridge at Simcoe Street, town of Oshawa.

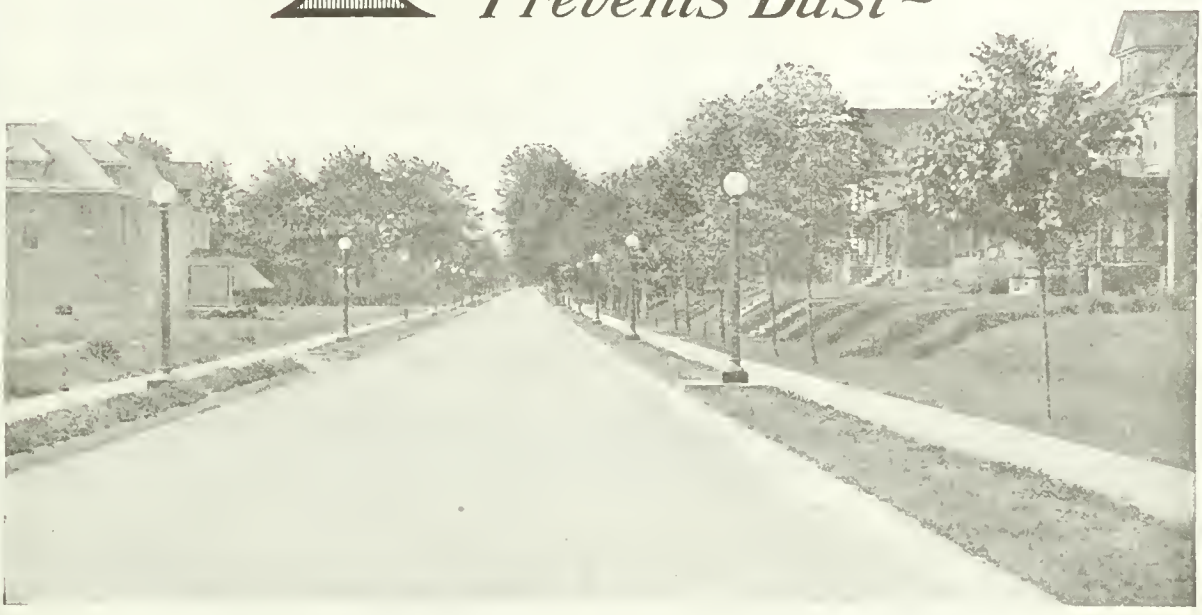
20996—December 12—Directing that crossing of tracks of Confederation Construction Company over G.T.R., be approved and authorized, for construction purposes only, subject to certain conditions. Temporary crossing be protected by an interlocking plant and derails be installed to satisfaction of Engineer of G.T.R.; Applicant Co., bear and pay entire cost of construction, maintenance and operation of crossing.

20997—December 11—Authorizing C.P.R. to open for traffic double track from mileage 76.8 to 84.2 on Moose Jaw Subdivision.

20998—December 11—Authorizing C.P.R. to open for traffic double track from Notman, mileage 95.1 to mileage 99.4, on Swift Current Subdivision.

Tarvia

Preserves Roads
Prevents Dust~



Brant Road, Galt, Ont., Canada. Constructed with Tarvia Modern Pavement.

Of Interest To Taxpayers

A cloud of dust behind an automobile means that the road surface is being destroyed—blown away. It also means that the road is unfit for modern traffic—that it has been built in the old way intended for slow-moving, horse-drawn traffic.

The science of MacAdam has been re-written these last few years. A mineral binder is no longer enough to hold the stone together.

Something stronger is needed, and the use of Tarvia is the logical and necessary answer to a difficult problem.

In the tarviated road, there is a matrix of Tarvia around each stone, holding it firmly to its work and preventing it from shifting. There is no internal movement, and the attrition of traffic is reduced to a minimum.

If the road is built with Tarvia the extra cost of the treatment is more than made up in longer life and reduced maintenance costs.

Tarvia is made in three grades—"Tarvia X" is a dense, viscid coal tar product of great bonding power, suitable for building macadam roads; "Tarvia A" and "Tarvia B" are thinner grades suitable for roads already in use, to preserve them and make them dustless.

RAILWAYS—STEAM AND ELECTRIC.

Aylmer, Ont.—The proposition of the London and Lake Erie Traction Company, to extend their road to Aylmer and Port Burwell was discussed at a meeting held recently in Aylmer, when representatives of the road met the representatives of the municipalities interested. The company's offer was placed before the meeting by Vice-President E. R. Wood. Mr. Wood considered that Aylmer should guarantee $20,000 per mile in bonds as her fair share, or $50,000 for the 2½ miles of line proposed, the guarantors to have the whole road as security. Mr. Wood stated also that the municipality of Port Burwell could be incorporated in the agreement, or any reasonable proposition would be considered by the company. The municipalities will consider the company's offer.

Barrie, Ont.—At a special meeting of the town council a provisional agreement with the Toronto, Barrie and Orillia Electric Railway Company was adopted and a by-law prepared for submission to the qualified ratepayers on January 5 to authorize a railway. The company gets a 25-year franchise and a fixed assessment of $15,000 for general taxation.

Calgary, Alta.—The C.N.R. has given notice through its subsidiary organization, the Calgary and Edmonton Railway Company, that at the next session of Parliament it will apply for permission to construct the following lines of railway:—From a point on the Macleod branch in township 19, 20 or 21, in a westerly direction to a point on the south branch of Sheep Creek, in range 4, west of 5th meridian, Alberta; from a point on the line described in paragraph (a) to a point on the north branch of Sheep Creek in range 2, 3 or 4, west of 5th meridian; from a point on the line described in paragraph (a) to a point on Trap Creek, west of 5th meridian The proposed line will go right through the heart of the new oil district.

Edmonton, Alta.—Private advices from London are that financial arrangements have been completed in England to build the Alberta, Peace River and Eastern Railway, from Hudson's Hope to the Pacific Ocean, 2,300 miles, by way of Edmonton and Peace River Crossing, with a branch line to Fort McMurray. The promoters of the railroad claim it will be the shortest transcontinental line on the North American continent. Surveyors have been over the proposed line between Edmonton and the Peace River country and it is announced that everything is in readiness to begin work.

Edmonton, Alta.—The construction of a line of railway from Edmonton to Alaska, was a proposition submitted to the Board of Trade, recently. The proposition met with approval, and it was resolved to have a committe appointed as soon as possible, with a view to pressing the further consideration of the matter upon the Dominion Government and with the ultimate intention of having the Government confer with the Government of the United States.

Edmonton, Alta.—Private advices from London are that financial arrangements have been completed in England to build the Alberta, Peace River and Eastern Railway, from Hudson's Hope to the Pacific Ocean, 2,300 miles, by way of Edmonton and Peace River Crossing, with a branch line to Fort McMurray. Surveyors have been over the proposed line between Edmonton and the Peace River country, and it is announced that everything is in readiness to begin work.

Edmonton, Alta.—The construction of a line of railway from Edmonton to Alaska is a proposition submitted to the Board of Trade by Mr. W. A. Griesbach. As he outlined it, the proposition met with approval, and it was resolved to have a committee appointed as soon as possible to press the further consideration of the matter upon the Dominion Government and with the ultimate intention of having the Government confer with the Government of the United States.

Fort William, Ont.—Details are completed for the building as rapidly as possible the last link of the Duluth and Minnesota Railway, which will connect the two lake ports, Fort William and Duluth. According to Engineer H. J. Hare, who is in charge of the construction, contractors will start at both ends of the connecting link early next spring, and the line will be rushed to completion. One hundred and twenty miles of the road have already been built from Duluth. Only 80 miles remain to be completed.

Guelph, Ont.—At the banquet held recently at Guelph of men from the city and neighboring counties, towns and villages, interested in the project of a radial to be operated by the Hydro-Electric Commission, it was resolved that the meeting representing some 25 municipalities of the counties of Wellington, Grey and Simcoe, urge upon the Hon. Adam Beck and his colleagues that they give these municipalities assistance in compiling all the necessary information as to cost of construction and operation, method of financing and most suitable location of said line, so that it may serve the best interests of the people of the district. And in return they guarantee that their earnest co-operation and support in the building up of such a Hydro electric radial system as shall bring the greatest development, progress and prosperity to the whole province of Ontario. In replying to the resolution, the Hon. Mr. Beck stated that the engineers of his department would, as soon as possible, go over the proposed routes. They would probably submit two or three plans, having regard to the feasibility of construction, and the number of people to be served.

MANNESMANN

SEAMLESS AND LAPWELDED

STEEL TUBES

Our tubes can be bent cold on the spot without trouble.

Our tubes can be supplied in lengths up to forty feet, thus effecting a large saving in joints, jointing material and labor.

Leakage is reduced to a minimum, as the joints are far tighter and seventy per cent. fewer.

Saving in freight, etc., is considerable, as a steel tube weighs one-third to one-half as much as a cast iron pipe of the same length. And there are other convincing reasons and illustrations in our booklets.

BOOKLETS ON REQUEST

MANNESMANN TUBE CO., LIMITED 51 Victoria Square **MONTREAL**

Hamilton, Ont.—C. W. Bell, solicitor for the Webb Incline, has announced that the company will begin at once upon the work of constructing a new incline, as ordered by the Ontario Railway Board.

Moose Jaw, Sask.—The G.T.R. and the C.N.R. have entered into arrangements for the erection of a Union Station and for the joint use of extensive terminal facilities at Moose Jaw. In the agreement the C.N.R. has secured running rights over the G.T.R. between Moose Jaw and Regina, which gives this city direct C.N.R. connection with Winnipeg and Fort William. The C.N.R. intends to construct a line from Moose Jaw running southwestward between Lakes Johnston and Chaplin to connect with the Midale extension running in the direction of Lethbridge, the expectation being that the connection will be made south of Maple Creek; and also a line connecting the city with Chamberlain on the Regina-Saskatoon branch, affording direct connection with Prince Albert by way of Saskatoon.

Montreal, Que.—The announcement is reported from headquarters that Mr. J. D. McArthur, railway contractor, Winnipeg, is interested in a railway project which aims to build in Saskatchewan a road from Regina southeasterly to the eastern boundary of the province; then northwesterly to townships 27, and thence northerly to Saskatoon—a local railway, for the convenience of the new settlers, which is to start with a capital of $1,000,000.

Ottawa, Ont.—The Canadian Northern Railway will ask Parliament for extension of time to build the following lines: Regina southwesterly to international boundary; Battleford westerly to the head waters of Brazeau River; Regina northerly to Humboldt, thence to Pas Mission, and from a point on the line between Humboldt and South Saskatchewan River northeasterly to crossing of South Saskatchewan River by company's Prince Albert branch; from Calgary westerly to Cochrane, Exshaw and Banff and from Cochrane northerly to intersect the company's line near Pigeon Lake; from Cochrane southerly to Nanton.

Ottawa, Ont.—The Canadian Northern Ontario Railway asks for extension of time to build the following lines:—(a) from its authorized line between Port Arthur and Sudbury, near the head of Long Lake, northerly and westerly to connect with the National Transcontinental Railway east to Lake Nipigon; (b) from its authorized line between Ottawa and North Bay, near the township of Chisholm, southeasterly to the Central Ontario Railway at or between Bancroft and Whitney; (c) also the line Port Dover to Kincardine.

Petrolea, Ont.—A rumor is circulated that the Merchant's Mutual Line and other lake package transportation freight companies are interested in plans for a railway route through Petrolea to Corunna, with radials to Courtright, Brigden, Arkona and Sarnia. The project is backed by London and Petrolea capitalists, and options for the right of way have already been secured on front farms in Moore township. Hydro-Electric is the proposed motive power, and it is figured that the amount of freight handled at once will more than compensate for the operation and equipment of the proposed road.

Port Arthur, Ont.—A by-law to raise the sum of $238,000 by way of debentures for the purpose of further improving and extending the street railway system of the city, will be submitted to ratepayers on January 5th next.

St. John, N.B.—The Hon. H. F. McLeod stated while here that the Valley Railway will cross the St. John River at The Mistake or Oak Point. At The Mistake, a diamond drill has gone down 200 feet into clear mud, without striking a bottom suitable for a bridge foundation. The railway will cross the St. John and the Kennebeccasis and connect with the Intercolonial at a point near Rothesay and thence over the I.C.R. to the Courtenay Bay district.

Toronto, Ont.—When in the city, Mr. J. Rose, an engineer who accompanied the survey party for much of the length of the new G.T.P. line between Calumet and a point near Belle River, which will make a short link with the main line from Montreal, stated that the preliminary survey of this 170 miles had been completed, and that it is expected that the new line of the Northern Railway between these two points will be commenced next spring, directly the bonds have been guaranteed.

Vancouver, B.C.—Recently Mr. J. J. Woods outlined the proposal of the promoters of a motorbus service in Vancouver before the civic finance committee. The final decision of the committee was that Mr. Woods draft an agreement setting forth just what was wanted from the city and how it was proposed to conduct the proposed service. This will be ready for the next meeting of the committee and if it is decided to recommend the granting of a franchise it will be submitted to the ratepayers in the form of a plebiscite, the expenses of which the promoters are prepared to defray.

Winnipeg, Man.—Tenders will be received up till December 29th, for the supply and delivery of 250,000 railway ties and 3,000 telephone poles. Plans and specifications may be obtained from the Office of the Commission for the Greater Winnipeg Water District, Winnipeg, Man. Signed, S. H. Reynolds, Chairman of Commissioners.

Winnipeg, Man.—Application will be made at the present session of the legislature for an act to incorporate a railway, with powers to construct railways and operate the same from a point at or near Fort Churchill to a point at or near the Hudson Bay Railway at Kettle Rapids, in the province of Manitoba, and all other powers and rights incident thereto.

GARBAGE, SEWAGE AND WATER.

Cedarvale, Ont.—A special meeting of the Cedarvale Ratepayer's Association is to consider the immediate need of a better water supply in the district.

Chatham, Ont.—The Hon. Adam Beck, at a recent mass meeting of Chatham ratepayers strongly advised the support of the by-law which will be submitted in January, to authorize the purchase by the city of the gas and electric light plant of the Chatham Gas Company in connection with the Hydro-Electric system in the city, the purchase price being $410,000.

Edmonton, Alta.—City Engineer Latorne reporting on the water and sewerage accommodation necessary in connection with the new city schools, states that it would cost approximately $12,700 to construct the permanent sewer for the H. Allan Gray School, as a long stretch of 36-inch and 24-inch intersecting sewer would be necessary; but an 8-inch temporary sewer along Westminster from the school to Namayo would cost about $2,300. The Bennett school can be taken care of with a sewer at a cost of $1,350. For the John A. McDougall School the engineer reports that the natural outlet is the 4-foot sewer now being constructed on Fifth Street. The additional permanent construction required to carry the sewerage from this school to this sewer would cost about $12,500, but a temporary sewer could be carried to the same point for about $4,620.

Hamilton, Ont.—The civic board of control has received a letter from the Fire Underwriters' Association to the effect that if Hamilton is to continue to pump water by electricity, it should duplicate its pumping equipment and obtain a supply of power independent of the Hydro-Electric power which is now being used.

Ottawa, Ont.—The waterworks committee has decided to have the city engineer spend $1,600 on completing the wall between the two aqueducts.

Peterborough, Ont.—The Trent Valley Water Conservation Association has been organized and the matter of conserving the waters of the district will be taken up with the Government.

Port Arthur, Ont.—Among other by-laws to be submitted to the ratepayers on January 5th, is one to provide for laying additional water mains and making extensions to the waterworks system, the cost to be covered by the issue of debentures for $202,167.

Regina, Sask.—When the city commissioners report on a cheap power scheme, they will recommend the adoption of the Coste-McCauley or Georgeson propositions for natural gas in preference to development of the Estevan coal fields for power purposes. Because of the high freight charges, they consider the latter too costly for success.

St. Catharines, Ont.—The Ontario Board of Health has directed the city of St. Catharines to establish a filtering system in connection with its waterworks, a mechanical filtration of the gravity type preferred, using storage period of two hours after administration of chemical.

Sydney, N.S.—The Dominion Steel Company are preparing to install a new heating furnace in their rolling mill de-

partment with a view to developing an output of soft steel in addition to the many other products at present manufactured at the works.

Welland, Ont.—Before the Niagara District Medical Association at the Welland Club, Dr. J. W. McCullough of Toronto, P.H.O., affirmed that the Government is investigating and making surveys for the laying of a pipe line from Port Colborne all along the canal to supply fresh lake water.

Winnipeg, Man.—The Winnipeg ratepayers have passed a by-law for the expenditure of $85,000 on an incinerator to be located in the district of Elmwood.

LIGHT, HEAT AND POWER.

Camrose, Alta.—Tenders will be received till December 22nd for plumbing, heating and ventilation for the Normal School at Camrose, Alta. Plans and specifications may be obtained from the Department of Public Works, Calgary. John Stocks, Deputy Minister.

Chatham, Ont.—The city council has dealt with the four by-laws to be submitted to ratepayers, among which are one to enable the council to sell debentures to raise funds for the hydro scheme, and one for the purchase of the Chatham Gas Company.

Fort William, Ont.—A by-law is advertised to be submitted at the coming civic elections to raise $115,500 by way of debentures for the purpose of taking care of the cost of improvements and extensions made and to be made to the electric light system at Fort William.

Hamilton, Ont.—A by-law will be submitted at the coming elections in Hamilton for the issue of debentures for $335,000 for the completion of the Hydro-Electric system in Hamilton.

Havelock, Ont.—It is understood that the Havelock council has decided to accept the suggestions of the Hydro-Electric Commission, and will embody them in a by-law to be passed on by the council and submitted to a vote at the January elections.

London, Ont.—A by-law is to be submitted to voters at the municipal elections to grant the right to Greene-Swift, Limited, to lay and maintain in certain streets in the city of London, pipes for the conducting of steam to supply heat to the inhabitants of the municipality.

Moose Jaw, Sask.—The city council has endorsed the proposal of William Georgeson and his associates to supply natural gas to Moose Jaw and has passed a resolution placing on record its approval of the project and recommending that the council of 1914 ratify the same.

+ **Nepawa, Man.**—Orders have been placed for the following apparatus for the town of Neepawa by their consulting engineers, W. E. Skinner, Limited, with the GOLDIE AND McCULLOCH COMPANY of Galt, Ont., for two 72 x 18 return tubular boilers and one 12 x 19 x 8 vertical compound condensing engine operating at 450 r.p.m.; and with the CANADIAN GENERAL ELECTRIC COMPANY for one a.t.b. 16, 150 k.v.a., 450 r.p.m., 2,400 volt, 3 phase, 60 cycle, A.C. generator.

+ **Ottawa, Ont.**—A contract has been awarded by the Cabinet Council to the ELECTRICAL REPAIR AND SUPPLY COMPANY for $990 for electric installation in a public building at Coaticook, Que.

Ottawa, Ont.—The city council has decided to leave the matter of the proposal regarding a municipal gas plant to next year's council, when there will be greater time for consideration.

Port Arthur, Ont.—A by-law to authorize extensions and improvements to the electrical power system and to issue debentures for $55,000 to cover the cost thereof, will be submitted to ratepayers on January 5th.

Vancouver, B.C.—A reorganization of the Ocean Falls Company in an amalgamation of Pacific Coast paper interests, that will put the Ocean Falls pulp plant in active operation again, and in addition mean the building of a $3,000,000 paper mill, is now in process of settlement, according to advices received in the city from London. It is proposed to form an amalgamation of the Powell River Pulp and Paper Company, the Crown Paper Company of Portland, the Quatsino Sound Pulp Company and the Ocean Falls Company, thus consolidating the Ocean Falls Company with the three largest pulp and paper properties on the Pacific Coast.

Victoria, B.C.—The civic authorities have been asked by the engineering firm of Du Cane, Dutcher and Company, to consult with the company's representatives for the purpose of arranging a 30-year franchise for a steam-heating plant in Victoria, which will utilize the waste material from lumber industries to generate heat and electricity for the supply of down-town office blocks. The council has appointed a committee to confer with the representatives of the company.

Wallaceburg, Ont.—At the January elections, a by-law will be submitted in Wallaceburg to secure authority for the purchase of the plant of the Wallaceburg Gas Company.

Welland, Ont.—At the next elections, there will be submitted to voters a by-law to grant the right to lay and maintain pipes for conducting natural or fuel gas or oil across and along the public highways in the township of Wainfleet, in the county of Welland, and to supply to the corporation of the inhabitants of the municipality or any of them natural or fuel gas or oil.

Winnipeg, Man.—The city of Winnipeg Light and Power Department are building a 12,000 volt transmission line between their substation and the G.T.P. shops in Transcona. The town's interest in this matter, as well as others of an electrical nature, are taken care of by W. E. Skinner, Limited, their consulting engineers.

Winnipeg, Man.—By a large majority, the Winnipeg ratepayers have approved the by-law granting $1,000,000 to the distribution section of the City Light and Power Department.

BRIDGES, ROADS AND PAVEMENTS.

Bow City, Alta.—The farmers of the adjoining country and the citizens are uniting to petition the Government for a bridge over the Bow River at this centre.

Calgary, Alta.—The city council has passed clause 4 in the proposed agreement between the city and the International Milling Company which stipulates that no work will be started upon the construction of 4th street subway, until the provincial legislature has ratified the whole agreement. This will probably delay the construction until the summer of 1915.

Galt, Ont.—Farmers who travel the East River road have circulated a petition to be presented to the Railway Board asking that the L.E. and N. Railway be forced to construct a subway at its intersection with the River road.

Montreal, Que.—The municipalities of Pike River, Stanbridge Station, Stanbridge East and Bedford, are urging upon the Government the urgency for the immediate construction of the Government highway starting from the King Edward road at Lacolle, in the county of St. Johns, through the counties of Missisquoi and Brome, as far as Knowlton, ultimately to connect with the Government highway from Sherbrooke to Derby Line.

Newcastle, N.B.—The Intercolonial authorities have decided to erect a bridge over the Miramichi between Chelmsford and Millerton, and surveyors are now at work taking the soundings of the proposed site.

New Westminster, B.C.—It is likely that work on the paving of Columbia Street in front of the penitentiary will be commenced this year. The distance to be paved is some 2,500 feet, and the Dominion Government is expected to pay $45,000, which is a good part of the total cost.

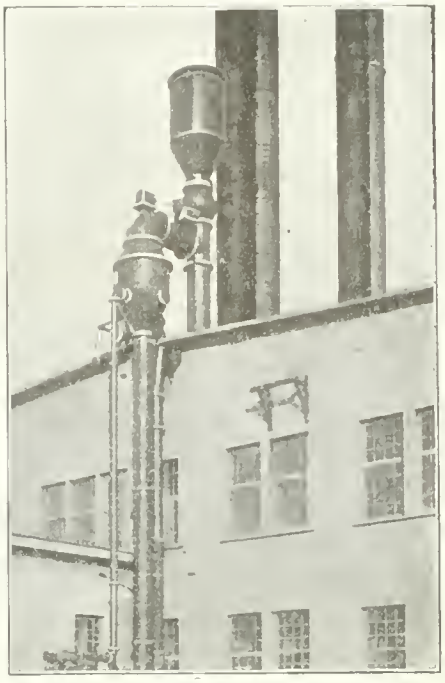
New Westminster, B.C.—The Navigation Committee of the New Westminster Board of Trade want the level of the new Government Pitt River Bridge raised ten feet above what is called for in the present plans. This would necessitate the lengthening of the apertures. A meeting of provincial authorities will consider the matter further.

Ottawa, Ont.—A report is to submitted to the board of control in which City Engineer Archibald Currie says that to put the various roads in Ottawa in good condition would require an expenditure of $3,172,119. In his report Mr. Currie gives a list of the various streets and the pavement proposed. He suggests 10 kinds of pavement and says that 84.32 miles of roadway would be involved—in other words, 445,258 lineal feet or 1,511,361 square yards. Mr. Currie recommends that

CONDENSING APPARATUS

specially designed to secure

GREATER STEAM ECONOMY



WORKS: WILLIAM and SEIGNEURS STREETS, MONTREAL

THE JOHN McDOUGALL CALEDONIAN IRON WORKS CO., Limited

Manufacturers of Boilers, Castings, Condensers, Elevators, Engines, Filters, Forgings, Hydraulic Machinery, Pumps, centrifugal and reciprocating, Steam Turbines, Tanks, Water Wheels, Water Works Plants.

Sewage Disposal

is best accomplished by means of

THE HAMPTON SEDIMENTATION TANK

This tank is not an experiment. It has been used at Norwich, England, for a number of years with most satisfactory results and has *proven* its efficiency and economy.

Used in connection with an electrolytic hypochlorite treatment, the process would be *absolutely odorless and the effluent free from disease germs.*

700 BULLITT BUILDING, PHILADELPHIA, Pa

the question of roadways in Ottawa be taken up very seriously as the present state of affairs is far from satisfactory.

Ottawa, Ont.—An agreement has been finally reached between the city Board of Trade and the county counsel respecting the building of a temporary bridge over the Rideau River at Billings Bridge. The terms were that the county would agree to the erection of a temporary bridge leaving to arbitration the division of cost from the south bank to the island; and that if it was proved that the county were also liable for a division of the cost of the part from the island to the north shore that the division of cost would be decided by arbitration. The agreement is to be ratified by the county council.

Peterborough, Ont.—The city council has decided to submit a by-law to the people at the January elections to provide for the construction of a $78,000 bridge from Dalhousie Street to Maria Street across the Otonabee River.

Saskatoon, Sask.—Up to date, no tender has been received for the rehabilitation of Long Hill from any of the firms asked to give an estimate on the work. The city commissioners believe that it would cost about $100,000. However, the question of using this money in the erection of a new bridge, which would solve the problem, is being raised and will be discussed by council.

Toronto, Ont.—Plans for the superstructure of the Bloor Street viaduct are being prepared and tenders will be called for early in the spring. A combination of problems have to be solved to make the viaduct accommodate the variety of traffic.

Toronto, Ont.—The new Gerrard Street bridge will cost between $182,000 and $198,000 more than the $200,000 which has been appropriated for it by the city, according to a report from the Works Department to the board of control.

Vancouver, B.C.—Tenders will be received up till December 23rd for the construction of certain asphaltic mixture and wood block pavements. Plans and specifications may be obtained from the City Engineer, City Hall, Vancouver, B.C. Signed, Wm. McQueen, City Clerk.

Vancouver, B.C.—At the last meeting of the Point Grey municipal council, it was decided that the intersections of Twenty-Seventh Avenue and Connaught Drive with Oak Street should be macadamized so as to make a better access from Oak Street to Braemar School.

Victoria, B.C.—A dual approach to the proposed Johnson Street Bridge, one from Johnson Street and another through property offered by the E. and N. Railway, connecting the bridge with Cormorant Street, was the proposition favored by the city council, which has again considered plans submitted by City Engineer Rust. The Government has declared its adhesion to the Johnson Street approach alone, but the council, in approving of the dual approach, expressed the hope that, at another conference with the Government, the city's choice will be approved. The engineers of the city and Government will be asked to get together with a view, if possible, to estimating the cost of the proposed structure so that a by-law may be submitted to the ratepayers at the forthcoming civic election; but first the location of the bridge must be fixed definitely.

INDUSTRIAL WORKS.

Bridgeburg, Ont.—It is rumoured that the M.C.R. will unite with the C.N.R. in the construction of a tunnel beneath the Niagara River, unless immediate steps are taken to double the International Bridge.

Cobalt, Ont.—Representatives of the Cobalt Lake Mining Company appeared before Mining Commissioner T. E. Godson recently to ask for a permit to drain Cobalt Lake. They wish to quarry in the bottom of the lake, the reason being that it would save miners from danger in tunnels.

Edmonton, Alta.—The city commissioners have concurred with the recommendations of City Engineer Latornel to leave the dredging of the channel across the river to his department to be done by day labor, rather than by contract.

Goderich, Ont.—The following recommendation is one of several made by the coroner's jury in the inquest at Goderich into the death of Thomas Stone, of the freighter 'John A. McGean': "We strongly recommend and believe that the government should without delay and at any cost complete and equip Goderich Harbor as a real harbor of refuge: first, by fully completing the breakwater now begun; second, by installing up-to-date lights and a fog signal at the entrance of the breakwall; third, by dredging to the necessary depth the outside basin formed by the breakwall so that ships may have some sea room after the stress of entering to manoeuvre and steady themselves before trying to enter the piers."

Megantic, P.Q.—Tenders will be received up till January 5th for the construction of a concrete dam. Plans and specifications may be obtained from the Clerk of the town of Megantic, County of Lake Megantic, P.Q. Signed, Joseph Roy, Clerk.

Ottawa, Ont.—Since tenders for a dam on French River have been called, it is expected that the Hon. Robert Rogers will shortly announce the appointment of a commission to inquire into the commercial feasibility of the canal project.

Ottawa, Ont.—Notice is given that the time for the reception of tenders for the construction of wharves at Victoria Harbor, B.C., has been extended to January 8th, 1914. Signed, R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Plans are being prepared by the Government for a new elevator at Calgary, and tenders will be invited early in the year. The capacity will be 2,500,000 bushels.

Sydney, N.S.—The Board of Trade terminal wharf committee is reported to be making great progress with their work in connection with that feature. The committee has already made an exhaustive study of the situation and is now preparing its report and other documents which will be submitted to the board.

Toronto, Ont.—The Harbor Commissioners have approved plans and specifications for improvements to be made at the mouth of the Don River and the construction of a lift bridge at Cherry Street. The work is to commence next April, and will be done by the Hargor Board by day labor, costing in the neighborhood of $294,000. At the mouth of the river, a permanent channel 125 feet in length is to be constructed to connect the Don and the bay. Also permanent concrete docks and every facility for shipping will be constructed. The lift bridge across the channel at Cherry Street will be of the "scissors" type, and will be built especially for highway and street railway traffic. The contract for this part of the work has not yet been let.

Vancouver, B.C.—A big, well-known cold storage company will build before spring a salting plant on Langara Island to handle all varieties of fish. Wharves and other necessities will also be built.

Vancouver, B.C.—The civic Board of Trade has passed a resolution to the effect "that the Vancouver Board of Trade, following its previous recommendation and resolution regarding the desirability of the Kitsilano and other Indian reserves bordering on the harbor being developed in the interests of harbor improvements under the authorization of the Vancouver Board of Harbor Commissioners, endorses the efforts of our member, Mr. H. Stevens, towards this end, believing this matter to be of supreme public importance and requiring the urgent attention of the government; and that this resolution be telegraphed to Rt. Hon. R. L. Borden."

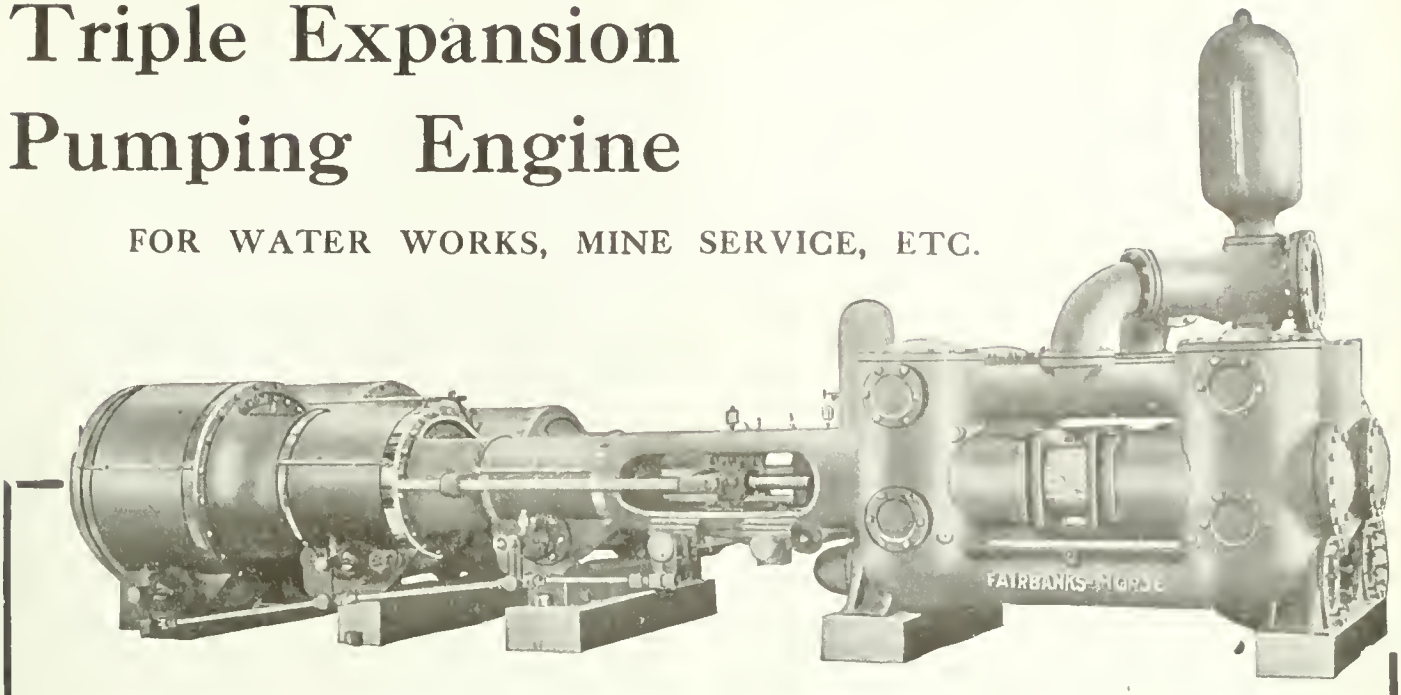
MISCELLANEOUS.

Chatham, Ont.—The city has defeated the by-law to provide for the raising of $25,000 for the purchase of three acres in the western part of the city, and bordering on the industrial spur, for factory sites.

Fort William, Ont.—A by-law to issue debentures for $30,000 with which to purchase and equip a rock quarry and to run an electric tramway to the site, will be submitted to the voters of Fort William at the January election. The members of the council had been considering a proposition submitted by the Mount McKay and Kakabeka Falls Railway Company to purchase that company's road, park and quarry.

Triple Expansion Pumping Engine

FOR WATER WORKS, MINE SERVICE, ETC.



The Fairbanks-Morse Triple Expansion Duplex Outside Centre Packed Plunger Pumping Engine shown here is very economical in the consumption of steam. The economy of operation makes this Pump preferable to all others in many situations.

The steam end is fitted with semi-rotative valves. The plungers being externally packed are always in sight and any leakage can be at once detected. All parts are easy of access. The stuffing boxes are large and deep, so that ample allowance of packing may be used.

This type of pump is heavily proportioned throughout in order to meet the demands of heavy service. It is designed to give long and satisfactory service at a minimum cost. It has a 24-inch stroke and a capacity of 2,500,000 gallons per 24 hours.

Departmentalising a Great Business

The marketing of one article is a very simple problem. As the number and variety of the products you sell increase, the complexity of your merchandising problem grows.

Our business has grown in the last dozen years from a comparatively few products into an enormous number of lines. This tremendous growth has necessitated the organizing of our business along departmental lines with able, efficient men at the heads of the various departments.

As organized now we can serve the mechanical field better than any house in Canada. In addition to being manufacturers, we are literally a large "departmental house for machinery and mechanical goods." This bringing together of a vast number of lines and classifying them according to departments is the kind of combination in industry that makes for efficiency, economy and better service.

It is just as great a convenience to Engineers, Contractors and Builders to be able to get their supplies from one House as it is to the general public to shop in a large, modern department store. In dealing with us you can get what you want "under one roof." Write, phone or call.

The Canadian Fairbanks-Morse Co., Limited

"The Departmental House for Mechanical Goods"

ST. JOHN QUEBEC MONTREAL OTTAWA TORONTO

the report that was to have been submitted by a special committee of the council, is not as yet on hand.

Fort William, Ont.—There will be submitted to ratepayers at the January elections a by-law to raise the sum of $125,000 by way of debentures for the purpose of further improving and extending the telephone system of the city.

Ottawa, Ont.—Tenders will be received up till January 7th for the purchase of the Canadian Government's patrol boats, "Hudson," "Davies," "Number One" and "Number Two." Persons desiring to examine the boats should communicate with R. Hockin, Inspector of Fisheries, Pictou, N.S., with Joseph Prescott, Fisheries Officer, Bay Verte, N.B., and with J. F. Calder, Fishery Officer, Campobello, N.B. Signed, C. Stanton, Esq., Acting Deputy Minister of Marine and Fisheries, Ottawa, Ont.

Ottawa, Ont.—Tenders will be received up till January 15th for 10 knots of gutta-percha cable with 4 conductors, and 14 knots of gutta-percha cable with 2 conductors, to be delivered at Halifax, N.S. or St. John, N.B., May 1, 1914. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

Sarnia, Ont.—Word has been received in Port Huron that a resolution has been passed authorizing the Secretary of War to go ahead with a survey of the St. Clair River on the American side, from a point near the tunnel to the mouth of Black River.

St. John, N.B.—On his arrival at St. John, Sir William Mackenzie confirmed the report that his company is contemplating the construction of two additional steamers for the Atlantic route.

Vancouver, B.C.—The Vancouver Board of Trade has endorsed the resolution passed by the Quebec Board of Trade asking the Dominion Government for a subsidy for a line of steamers between Eastern Canada and the Pacific Coast.

+—Victoria, B.C.—The contract has been let by the Empire Lumber Company, of New York, to E. R. DOE, of Victoria, B.C., for a booming ground and a 1,000-foot unloading trestle at Osborne Bay, to cost $20,000.

+—Victoria, B.C.—The contract has been let by the Empire Lumber Company, of New York, to GEORGE McDONALD for the construction of a 100 h.p. tug, to be built at Cowchan Bay.

Victoria, B.C.—The Pacific Coast Steamship Company's steamer "City of Seattle," of the Alaska fleet, is now at the yard of the Seattle Construction and Drydock Company, having new boilers installed. These boilers are of the Scotch marine type, 13 feet diameter by 13 feet 10½ inches long, aggregating a total heating surface of 4,280 square feet. Each boiler is equipped with three Morison suspension furnaces. In addition to the installation of new boilers, the owners intend to have the entire superstructure from stem to stern reconstructed of steel. This contract will be awarded at an early date.

Winnipeg, Man.—Tenders will be received up till December 26th for the construction of an icebreaker and navigation fender at the Louise Bridge. Plans and specifications may be obtained from the City Engineer, 223 James Avenue, Winnipeg, Man. Signed, M. Peterson, Esq., Secretary, Board of Control.

CURRENT NEWS.

Brandon, Man.—The balanced gates to be placed at the First Street crossing of the C.N.R., by order of the requirements of the Board of Railway Commissioners, are ready and awaiting installation.

Brandon, Man.—The wiring work for the street railway is practically completed for this year.

Calgary, Alta.—According to figures compiled by oil men of this city, contracts have already been let for the drilling of no less than 16 wells in the Okotoks and Aldersyde oil fields. Adding the three wells which are now being drilled to this number, the total is brought up to 19. These contracts call for the commencement of drilling operations either this winter or early next spring.

Fort William, Ont.—Work is progressing rapidly on the stub street railway lines from the main line to the garbage collecting stations on Walsh and Young Streets. The branches are standard double track and each is 1,600 feet long. Collecting stations and the lines connecting them with the main system will be in readiness to handle garbage as soon as the incinerator plant is completed. This construction is going ahead rapidly, and it is predicted that it will be completed in about three weeks. Specially made street cars, in which garbage will be conveyed from the collecting stations to the burning plant, arrived several weeks ago.

Fort William, Ont.—As a result of a decision unanimously arrived at by the city council, the Canadian Iron Corporation, Limited, which had contemplated shutting down for the winter, will operate a couple of months or more longer. This has been affected through the execution of the city's order for cast-iron pipe ranging in size from 18-inch to 8-inch, and amounting to 1,600 tons, at a cost of about $72,000.

Fort William, Ont.—Until two large bridges have been completed, track laying on the C.N.R. east of Port Arthur cannot proceed and a gap of nine miles remains unfinished. It is expected that the bridge at mile 244 will be finished before Christmas, and that track will then be laid to the second one at mile 253, which will likely be completed about the same time that steel will have reached it. From Port Arthur to mile 200 the track is all ballasted, while beyond mile 200 it has been given one lift of ballast. All stations, section houses and water tanks up to mile 200 have either been completed or are under construction. Next summer considerable finishing work will have to be done, but the bulk of the work is over. Grading is very heavy with considerable rock cutting, but the low grades and curvatures, decided upon at first, have been adhered to. The line between Sudbury and Oba is practically completed and the gap is between Port Arthur and Oba.

Levis, Que.—Mr. Davie, of Geo. T. Davie and Son, who have a shipbuilding and drydock plant at Levis, has announced that his firm was preparing to tender for the construction of the mammoth ice-breaker that the Canadian Government will have built next year. The Canadian Vickers Company are also tendering. The contract will be awarded early in January.

London, Ont.—At the first meeting of the commission recently appointed to take charge of the affairs of the electrified London and Port Stanley Railway, Hon. Adam Beck was given the chairmanship of the commission and Mr. Philip Pocock, who is now chairman of the Water Commission of London, was made vice-chairman; Alderman William Spittal, secretary pro tem. Colonel Lamb, of Windsor, representing the Dominion Public Works Department, was present and produced plans for a warehouse, which is to be built at Port Stanley wharfs. The Government, he announced, will also replace the old east dock with a new one and will widen the channel during the coming season.

London, Ont.—Owing to good weather, Bain and Ross, the contractors on the new Wharncliffe Road bridge, are making progress and will soon have the abutments completed to allow the Hamilton Bridge Company to go ahead with the steel work, which can be done in winter months.

Montreal, Que.—The C.P.R. new line between Glen Tay and Agincourt, making the double track between Montreal and Toronto, is expected to open for freight toward the close of the present month. Passenger trains will be running over it next spring. It is very free from grades, and all the work in the connection is of the most massive and permanent character.

Montreal, Que.—The engineers in charge report good progress on the Montreal and Southern Counties Railway line. From Marieville to St. Cesaire, the roadbed is complete, the bonding, the poles and brackets and all equipment is in position, and the overhead wire is being strung. A fine new station is being erected at Rougemont, which is about half-way between Marieville and St. Cesaire. The bridge over the Yamaska River east of St. Cesaire, being built by Mr. John Ross, is well under way, and will doubtless be completed in the early spring. Already the coffer dams are nearing completion, and a great deal of concrete has been put in position.

Newcastle, N.B.—Work at the new wireless station is proceeding rapidly. The six wooden towers, each 300 feet high, have now been completed and about 60 feet of the central steel tower, which will be 500 feet high have been erected. The power house and offices are also well advanced:

Cost of pipe = 20% cost of work
Saving by using poor pipe = 20%
Saving on total cost = 4%

IS IT WORTH WHILE?

If the sewer is to cost $10,000, for instance, MIMICO pipe would likely not cost more than $2,000, probably considerably less. Not more than $400 could be saved on this pipe cost by purchasing a poor grade of pipe. You would then have a poor sewer costing $9,600, when for $10,000 you might have had the very best sewer possible to build. Is it worth while to buy poor pipe? No! Then buy Mimico Brand and put an end to sewer troubles.

Prices on request.

Suspension Bridges

By WILLIAM H. BURR, Professor of Civil Engineering in Columbia University, in the City of New York. 8vo, xi. + 407 pages. Cloth $4.50 net.

In this book each main structure has been given a general treatment so as to make one demonstration cover all desired or useful special cases, as conducing to both brevity and clearness.
Treats on the statically indeterminate stiffening-trusses; theory of the straight stiffening-truss based on the method of deflections; terminal stresses; arch ribs treated by graphical methods; the general analytic theory of elastic arch ribs according to the law of least work; three-hinged arch ribs; braced spandrel arch, and cantilevers.

Graphics and Structural Design

By H. D. HESS, M.E., Professor of Machine Design, Sibley College, Cornell University, formerly Designer and Computer for the Mechanical Department of the Pencoyd Iron Works and the American Bridge Company, Member American Society M.E. 8vo., viii. + 426 pages, 429 figures. Cloth $3.00 net.

Knowledge of this subject is indispensable to the general designer.
Although the book is called "Graphics and Structural Design," the determination of the stresses has not been confined to graphical means; the other usual methods have been included.

Earthwork Haul and Overhaul

Including Economic Distribution.
By J. C. L. FISH, Member American Society C.E., Professor of Railroad Engineering, Leland Stanford Junior University. 8vo., xiv. + 165 pages, 66 figures. Cloth $1.50 net.

This work presents answers to all questions on computations of overhaul and on the use of the mass curve in planning distribution.

Elements of Heating and Ventilation

By ARTHUR M. GREENE, JR., Professor of Mechanical Engineering, Rensselaer Polytechnic Institute. 8vo., vi. + 324 pages, 223 figures. Cloth $2.50 net.

Brings together in logical order and in a small volume the necessary data from which to design the heating and ventilating systems of buildings.

Elements of Heat-Power Engineering

By C. F. HIRSHFELD and WILLIAM N. BARNARD, Sibley College, Cornell University. 8vo., xiii. + 811 pages, 480 figures. Cloth $5.00 net.

Includes the elementary thermodynamic theory of gases and vapors and of their cycles; also the consideration of the sources of heat and the methods of making it available for useful purposes.

The Renouf Publishing Company
25 McGill College Avenue
Montreal

and if given favorable weather, the station should be completed early in the New Year.

Newport, B.C.—A recent heavy gale at Newport broke the dyke and flooded the town. In addition, a portion of the Government wharf was carried away; and it is now impossible for vessels to approach. it.

Ottawa, Ont.—Mayor Ellis, representing the municipal electric commission, states that under the new contract with the Hydro-Electric Commission, the city will save $10,000 on the cost of electricity. The Hydro-Electric Commission's engineers are of opinion that until there is a much larger market for power in Ottawa and its vicinity that at present it would not be economical in any event to develop the Chats Falls. However, it is the intention of the Hydro-Electric Power Commission to go on with the acquisition of the Chats Falls so that they can be held and developed whenever there is a sufficient market for the power to enable the development to be made at a price better than that at which it can be purchased.

Ottawa, Ont.—Dr. P. J. Maloney, of Cornwall, provincial officer of health for Eastern Ontario, has declared that the city incinerator inadequate for present needs, and that it must be either enlarged, improved or some other method used to prevent the city from creating a nuisance by the manner in which the garbage is disposed of.

Peterborough, Ont.—The offer of the Peterborough Light and Power Company to supply power to the municipality to operate the magnetic arc lights, was approved by both the Hydro-Electric Commission and the civic authorities; and a feed wire capable of supplying an unlimited quantity of power has been connected with the rectifiers of the municipal substation. It is estimated that about 70 h.p. is necessary; and on December 33rd it is expected the power will be turned on and the streets lighted.

Peterborough, Ont.—The contractors engaged in the work of constructing the new C.P.R. bridge across the Otonabee River expect to have the structure completed by Christmas. The middle span, which will be a swing section, will not be erected until next fall. This is due to the fact that a swing bridge was not demanded until the plans for a stationary bridge had been completed. It is understood that the company will construct what is known as a bob-tailed swing, which will provide for a 37-foot channel.

Quebec, Que.—It is said that the Federal Government has acquired the old Quebec Gas Works from the Q.R.L.H. and P. Company, at a cost of $750,000. The Government will utilize part of the property purchased in connection with its scheme for improving the St. Charles River and part in connection with the plans for the proposed union passenger station.

Regina, Sask.—It is expected to have the paving of the west side of the new Broad Street subway completed before Christmas and the subway opened for traffic.

South Vancouver, B.C.—The purchase of a 75 h.p. electric motor for the waterworks department, at a cost of $742, was authorized by the recent meeting of the municipal council.

Toronto, Ont.—The Hydro-Electric Commission has reduced the cost of power in the following municipalities, thus: —Hamilton, from $16 to $15 per horsepower; Dundas, $16 to $15; Caledonia, $29.10 to $24; London, $24 to $23; Guelph, $22 to $21; Preston, $21.50 to $21; Galt, $22 to $21.50; Waterloo, $23.50 to $22.50; Berlin, $22.50 to $21.50; Baden, $37 to $32; St. Thomas, $29 to $28; Port Credit, $31 to $28.

Vancouver, B.C.—Sir Richard McBride has stated that, though more than 2,000 miles of new railway construction is being undertaken in British Columbia, no company under agreement with the Government has so far asked for a day's extension of time, and it is not expected that any company will approach the Government for an extension.

Victoria, B.C.—Work on the completion of the paving of Douglas Street is being carried ahead as rapidly as the uncertain weather conditions will permit, and it is expected will be almost completed by the end of the present week. When this paving is finished the city street work for the year will be practically completed, and, so far as paving is concerned, no more will be done until next year.

Victoria, B.C.—Work on the repair of the sewer on Oxford Street is being rushed by the city engineer. Owing to the nature of the ground, a large number of piles will be driven to support the sewer when relaid. Some of these piles have had to be driven down 29 feet before touching firm foundation. While the city has appropriated $8,000 for the work, it is a certainty that before the whole job is completed it will cost several times that figure.

Victoria, B.C.—Work has been commenced on the northwest sewer at Macaulay Point, being the first place in which the sewer has been commenced in the limits of Esquimalt municipality.

TRADE ENQUIRIES.

The following inquiries relating to Canadian trade have been received:—2249.—A South African importer wishes to be put in touch with Canadian manufacturers of shovels. 2250.—Samples and prices are asked for by a South African importer in Canadian-made fencing wire. 2266.—An East London general merchant would like prices and samples of wire. 2292.—Samples and quotations on barbed wire are asked for by a Durban firm. 2305.—A South African firm requests samples on cards and quotations for Canadian-made wire, barbed and plain. 2307.—Catalogues and prices are requested by Durban firms on Canadian manufactured tools. 2308.—Catalogues and quotations on axes, are requested by a Durban firm.

The names of the firms making these inquiries, with their addresses, can be obtained upon application to: "The Inquiries Branch, the Department of Trade and Commerce, Ottawa," or the Secretary of the Canadian Manufacturers' Association, Toronto, or the Secretary of the Board of Trade at London, Toronto, Brandon, Halifax, Montreal, St. John, Sherbrooke, Vancouver, Victoria, Winnipeg, Calgary and Chambre de Commerce du District du Montreal.

The following inquiries relating to Canadian trade have been received:—

2172.—Samples and prices of wire are asked for by a South African firm of importers. 2190.—Inquiries are made by a South African firm of importers for catalognes and prices on Canadian-made shovels. 2229.—A Yorkshire manufacturing company is in the market for amber mica, and would be glad to receive samples and quotations from Canadian producers. 2231.—An important London firm of mineral brokers are looking for further supplies of molybdenum, chrome ore, wolfram and tin ores and are open to consider offers of regular shipments of these ores from Canadian producers. 2232.—A firm in Hamburg, Germany, who handle mica, invites offers and quotations from Canadian shippers. 2234.—A firm in Bordeaux, France, having extensive connections in steel and iron industry wishes to get into touch with producers of above-mentioned iron ores. 2235.—An agent in Paris with connections in coal and steel trade desires to be put in touch with producers of molybdenum iron ore.

The names of the firms making these inquiries, with their addresses, can be obtained upon application to:—"The Inquiries Branch, the Department of Trade and Commerce, Ottawa, or the Secretary of the Canadian Manufacturers' Association, Toronto, or the Secretary of the Board of Trade at London, Toronto, Brandon, Halifax, Montreal, St. John, Sherbrooke, Vancouver, Victoria, Winnipeg, Calgary and Chambre de Commerce du District du Montreal."

MEXICAN EAGLE ASPHALT

TRADE MARK

East Main Street, Hamilton, paved with Mexican Eagle Asphalt

MEXICAN EAGLE ASPHALT is specially adapted to the Canadian climate, as it is not susceptible to changes in temperature and will not mark in the hottest weather. Dow and Smith, Consulting Paving Engineers, say: "This is a very high quality of asphalt."

EVERY BARREL of our asphalt is guaranteed to be uniform and according to analysis. This is the guarantee of our principals, the Mexican Eagle Oil Co., Limited, a company that has over twenty-five million dollars working capital.

Our asphalt in not dependent on the whims of nature. It is refined by the most accurate scientific processes from excellent asphaltic materials. That is why it is much less affected by extremes of cold or heat than is California, Trinidad, Bermudez or any other asphalt on the market. It is a favorite for its high purity, cementing value and ductility.

We can also supply different grades of Mexican Asphalt for asphalt fillers, road binders, roofing asphalts, wooden water pipe coatings, waterproofings, etc. Also Durazzo Sicilian Rock Mastic Asphalt for sidewalks.

Samples, prices, analyses, etc., on request

TRANSPORTATION BUILDING — MONTREAL

TENDERS CALLED FOR

Sealed tenders addressed to the undersigned, and endorsed, "Tender for Dam on French River, South Channel, Ont.," will be received at this office until 4.00 p.m., on Monday, December 29, 1913, for the construction of a Dam across the South Channel of the French River, at head of Big Chaudiere Falls.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the offices of the District Engineers, Confederation Life Building, Toronto, Ontario; Post Office Building, Montreal, and on application to the Postmaster of North Bay, Ont.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, December 5, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—51842.

CITY OF OTTAWA, DOMINION OF CANADA.

TENDERS FOR STEEL PIPES.

Sealed tenders in duplicate addressed one copy to the City Clerk, City of Ottawa, Canada, and the other to Sir Alex. Binnie, Son and Deacon, St. Stephens House, Westminster, London, England, and endorsed, "Tenders for steel pipes," will be received until 4 p.m. on Tuesday, the 3rd day of February, 1914, for about forty-two miles of steel pipe, fifty-four inches internal diameter, about thirty-two miles of steel pipe, fifty-eight inches internal diameter, and about eleven miles of steel pipe, fifty-one inches internal diameter.

Forms of tender and specification may be obtained from Sir Alex. Binnie, Son and Deacon, St. Stephens House, Victoria Embankment, London, S.W., or from the City Engineer of Ottawa, Canada, on and after the fifteenth, on receipt by them of a cheque to the value of five hundred dollars, made out to the City Treasurer of the City of Ottawa, Canada, which sum will be returned on receipt of a bona fide tender.

The lowest or any tender is not necessarily accepted.

No tenders will be considered except from actual manufacturers capable of supplying the whole of the pipes within a period of two and a half years from the date of acceptance of the tender.

SIR ALEX. BINNIE, SON & DEACON,
Engineers in Chief,
St. Stephens House,
Westminster, London.

Dated December 4th, 1914.

Sealed tenders addressed to the undersigned, and endorsed "Tender for Submarine Cables," will be received at this office until 4 p.m., on Thursday, the 15th January, 1914, for 10 knots of gutta-percha cable with 4 conductors and 14 knots of gutta-percha cable with 2 conductors to be delivered at Halifax., N.S., or St. John, N.B., by the 1st of May.

Specification and forms of tender can be obtained on application to the office of the General Superintendent of the Government Telegraph Service at the Department of Public Works, Ottawa.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 per cent.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, December 9, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—51974.

EXTENSION OF TIME.

Notice is hereby given that the time for the reception of tenders for the construction of wharfs at Victoria Harbor, B.C., is extended to Thursday, January 8, 1914.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, December 9, 1913.

NEW INCORPORATIONS.

Saskatoon, Sask.—Northern Brick and Supply Co., Limited, $150,000. Argue, Limited, $20,000.

Sherbrooke, Que.—Two Miles Falls Water Power Co., $500,000. I. L. Lafleur, J. E. Roberge, O. E. Dorais.

Windsor, Ont.—Moloney Electric Company of Canada, Limited, $300,000. R. W. Hart, A. Chenier, P. Stokes.

Kingsville, Ont.—The Champion Brick and Tile Co., Limited, $75,000. D. Wigle, R. M. Wright, G. Pearse.

Collingwood, Ont.—The W. A. Tom Construction Co., Limited, $45,000. J. T. Loftus, W. H. Ford, A. I. Naftel.

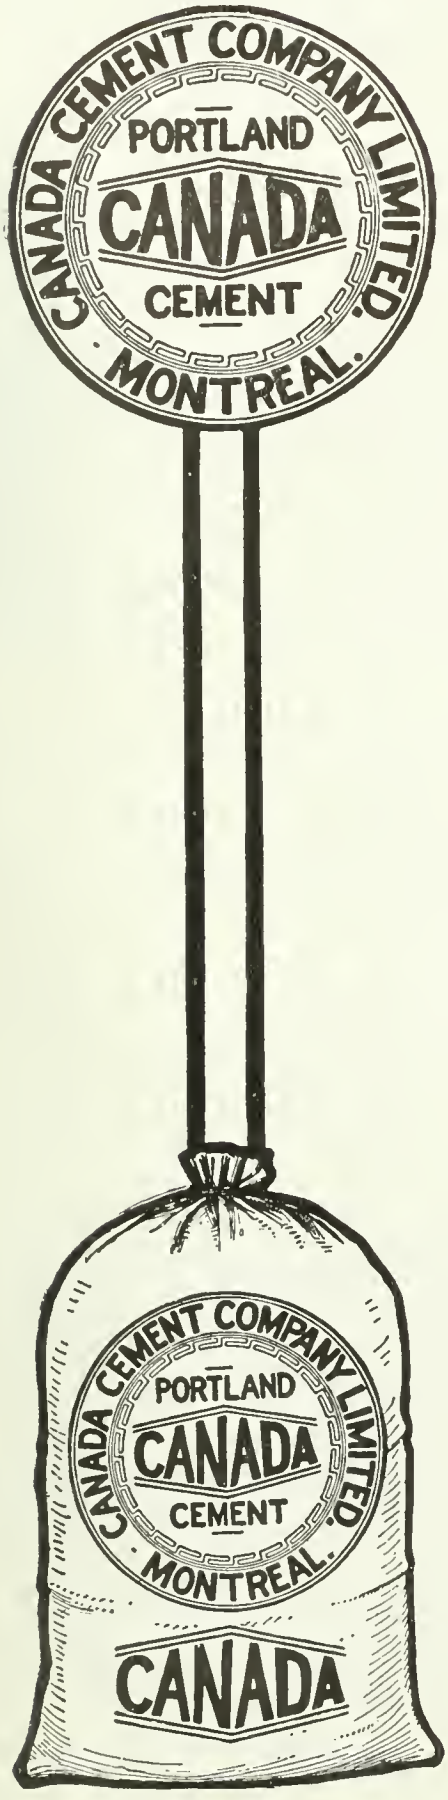
Montreal, Que.—Brick and Construction Products Co. of Montreal, Limited, $600,000. P. Taschereau, T. Rinfret, N. Z. Cordeau. Transcontinental Construction Co., Limited, $50,000. W. J. White, A. W. P. Buchanan, T. S. Owens.

PERMANENCE—



an ideal that is now attainable

THE superiority of concrete over all other materials for the building of permanent structures is now generally admitted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

Contractors' Machinery For Sale Or Rent

We have in stock the following second-hand equipment for immediate delivery.

Send for details and prices.

1—8"x 10"x 8" steam driven air compressor.
1—6" x 5" x 7" steam driven air compressor.
1—9" x 10" double cylinder, belt driven ai compressor.
1—No. 3 Ransome concrete mixer.
1—No. 2 Ransome concrete mixer.
18—concrete carts.
1—7"x10" dble. cyl., dble. drum steam hoist.
1—6½" x 8" double cylinder, single drum steam hoist.
1—5"x6" dble. cyl. single drum steam hoist.
1—6" belt driven centrifugal pump.
1—5" belt driven centrifugal pump.
1—60 H.P. firebox boiler on wheels

DRAUGHTSMAN desires employment, engineering, surveying, architectural, Montreal reference; fifty dollars. Special lettering and tracing, diplomas. W. J. Collins, 129 Bleury Street, Montreal.

MONTREAL MARKET LETTER.

Montreal, December 10th.

The heads of both the Dominion Steel Corporation and the Nova Scotia Steel and Coal Company were in Montreal during last week, and this naturally attracted more than usual attention to the iron and steel situation. Mr. Plummer was here to attend the meeting of the directors of the Dominion Steel Corporation, this meeting being the regular quarterly dividend meeting. Previous to the meeting the report reached the Street that the dividend would either be passed or cut, and consequently there took place a marked decline in the stock of the corporation. The dividend, however, was declared as usual. An interview given out by Mr. Plummer was to the effect that the various plants of the corporation were now in an advanced state of perfection, and that hereafter it would not be necessary to make application for more capital for a couple of years to come. The wire rod mill was closed down and the rail mill was running, though there were not as many orders on hand as a year ago. Mr. Plummer thought that the railways would shortly begin to give out further orders for supplies.

President R. E. Harris of the Scotia Company was here last week for a couple of days. The stock of that company also showed an easier disposition and declined a couple of points. It is not knowed what caused the weakness in the stock, inasmuch as there was every reason to believe that the company was earning its dividend, although this company would naturally be subjected to the same general conditions as the Dominion Steel Corporation; and it is only natural to suppose that the falling off in trade activity and the tendency of prices to decline would have a considerable effect upon the profits.

There was nothing new in the way of price changes or trade developments. Buying was dull all the way round. Some of the car companies, it was claimed, had quite a few orders on hand, but assuming this report to be true, it, in reality, did not affect the general situation, for the reason that it is well known that orders for cars are not being given out as they were a year ago, and that unless railways soon begin to give out new orders, the car works will show marked falling off in activity before a great length of time.

PATENTS.

The following is a list of patents recently issued through the agency of Messrs. Ridout and Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained:—

Canada.—Frederick Hansen, engines; Mario W. Tebyrica, railroad ties and beds; Olof Soderlund and Teofron Boberg, evaporating, distilling and similar installations; Nils Testrup and Thos. Rigby, production of wet carbonizing briquettes; George C. Adams, throttling devices for pipes, tubes and pumps; George J. Ogden, electric switches.

United States.—James M. Wilson, rotary pumps and motors.

Newfoundland.—Callendars Cable and Construction Co., supports for electrical conductors.

ONE OF OUR RECENT BRIDGE CONTRACTS

CONSTRUCTED IN NINE MONTHS

Substructure of a 930 ft. Double Track Railroad Bridge—Under very difficult conditions, these piers were carried to a maximum depth of 50 ft. below water level, by pneumatic caissons and open cofferdams.

THE FOUNDATION COMPANY

MONTREAL LIMITED VANCOUVER

MARKET CONDITIONS

Montreal, December 15th, 1913.

Bar Iron and Steel—Trade is reported active. Bar iron, $2.05 per 100 pounds; best refined horseshoe, $2.30; forged iron $2.20; mild steel, $2.15; sleigh shoe steel, $2.15 for 1 x ⅜ base; tire steel, $2.25 for 1 x ⅜ base; toe caulk steel $3; machine steel, iron finish, $2.25.

Cement—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1 40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in. $4.70; ⅜ in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3 45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3 15; 1-in., $3.05.

Explosives and Accessories—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25 lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength per 100 fuses:—4-ft. wires, $3; double strength, $3 50; 6-ft. wires, $3.54, and double. $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4 30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge. American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $21.75 per ton; selected Summerlee, $21 25; soft Summerlee, $20.75 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19 to $19.50 per ton, on track.

Lath—See Lumber, etc.

Lumber, etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 56 to 55c. each. Telegraph poles: seven-inch top, cedar poles, 25-ft. poles, $2, each; 30 ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per font. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce 4-ft. x 1½ in., mill run, $3 to $3.25; pine 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions, as laths, X, $2 10; XX, $2.40 XXX, $2.80.

Pipe—Cast Iron—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe—Wrought and Galvanized—Demand is fair and the market steady:—¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent off for black and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22 50; 1½-inch $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57 50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. off for galvanized: 3½-inch $95 4-inch $1.08.

Toronto, December 17th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes—Orders continue active. Lap-welded, steel, 1¾-inch, 10c. 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks—In active movement. The price is $11 50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $16 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $14 to $15 per M., three grades.

Broken Stone—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c per ton of 2,000 lbs., either 1-inch, 10c., 2-inch or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for gond Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto 60 cents.

Cement—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks, 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c to 24½c. per lb.

Detonator Caps—75c. and $1 per 100; case lots, 5,000, 20 per cent. off.

Dynamite—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents per pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cents.

Fuses—Electric Blasting—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain—¼-inch, $5.75; 5-16-inch, $5.15; ¾-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40 60; 6-inch, $52.64. Galvanized Pipe, ¼-inch, $2.86; ⅜-inch, $2.86; ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead—Firmer, $5.25 to $5.50.

Pig Iron—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green $8, with a prospect of advance. Dealers are fairly busy.

Sand—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0 25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. traps	2.00	3.20	6.50	15.00	....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes 9 inches and under, or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels—Active—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2 75 to $3 per 100 lbs. Extra for smaller sizes of angles and tees.

Sheet Copper—22c. per lb.

Sheet Steel—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized—Apollo Brand—Sheets, 6 or 8 feet long, 30 or 36 inches wide: 10-gauge, $3; 12-14-gauge, $3; 16, 18, 20, $3.30; 22-24, $3,40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 lbs. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin—The combination seems to hold, and the price 45 to 50c., lower.

Tool Steel—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates—3-16 inch, $2.40 per 100 lbs.

Zinc—Spelter—Good demand, and the feeling strong. Light stock; excelle demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, December 16th, 1913.

Anvils—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¾ to 10¾c., anvil and vise combined, each $5.50.

Bar Iron—$2.50 base.

Bars—Crow, $4.50 per 100 pounds.

Beams and Channels—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick—Kiln run per M, $13; sewer pipe per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland—$2.40 to $2.50 per barrel.

Chain—Coil, 3 16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7.16, $4.75; ½, $4.50, 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¼c. Tie out, 70 and 10 per cent.

Copper—Tinned, boiler, 26½c., planished, 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent. discount.

Dynamite—$11 to $13 per case.

Galvanized Iron—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20 $4; 18 $3.95; 16, $3.90. Queen's Head, 28, $4.80; 26, $4.70; 24, $4.80 22, $4.30; 20, $4.10 per cw

Iron—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26 gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 28-gauge American $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.25; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7 80; 1½-inch, $9.35, 2-inch, $12.50; galvanized—½-inch $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled—3-16-in. $3.35 base; machinery, $3 base; share; $4.50 base; share crucible, $5.50; cast share steel, $7.50; tire cast, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel—8½ to 15c. per pound.

BRIDGE CONSTRUCTION AT NEWCASTLE, N.B.

DESCRIPTION OF THE FOUNDATION WORK OF THE MIRAMICHI RIVER HIGHWAY BRIDGE — BUILT ON TWO ABUTMENTS AND FIVE PIERS OVER 1400 FOOT CHANNEL—OPEN CAISSON DREDGING METHOD USED

By C. A. WENTWORTH

AN interesting piece of bridge foundation work is being built for a highway bridge across the Miramichi River at Newcastle, N.B. Newcastle is situated about thirty miles from the mouth of

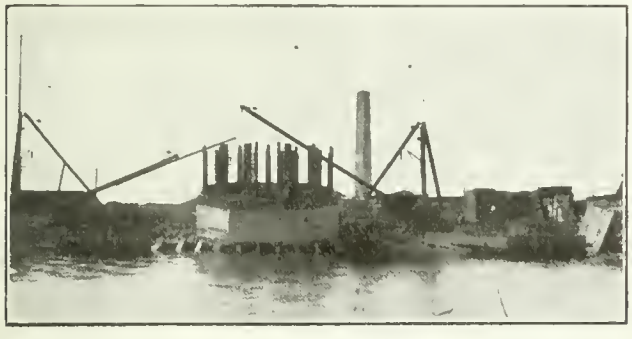

Fig. 1.—Pivot Pier Caisson Ready for Launching.

the river and is a growing town of 3,000 inhabitants. Across the river is the town of Nelson, and six miles below, on the Nelson side, is Chatham, whose population is slightly larger than that of Newcastle.

The river varies from three miles wide near the mouth to about one-half mile wide at Newcastle. The

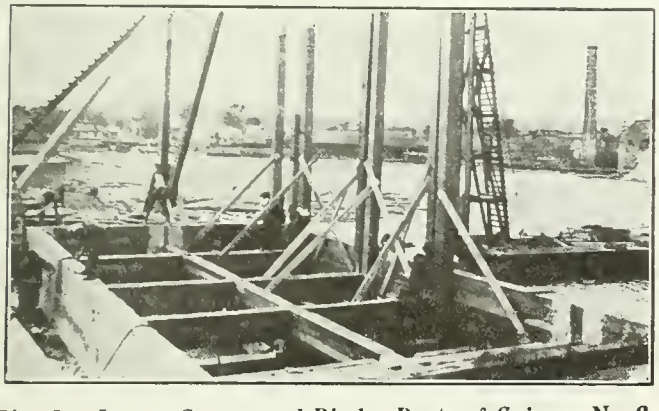

Fig. 2.—Lower Course and Binder Posts of Caisson No. 2.

nearest highway bridge to the mouth of the river is at Indiantown, over forty miles from the mouth and about fifteen mines from Newcastle.

Four to five months in the winter the river can he used as a highway, as the ice is usually 30 in. to 36 in. thick; and for a slightly longer time in the summer ferry boats cross the river at both Newcastle and Chatham, but for a month or more in the fall and spring there is no way of crossing. The important lumber and manufacturing interests all along the river made the construction of a bridge a necessity to accommodate the important interests of the people in this section of New Brunswick.

After careful examination by diamond drill borings, the location was decided upon opposite Newcastle and about one mile downstream from the confluence of the southwest branch with the northwest branch of the Miramichi River.

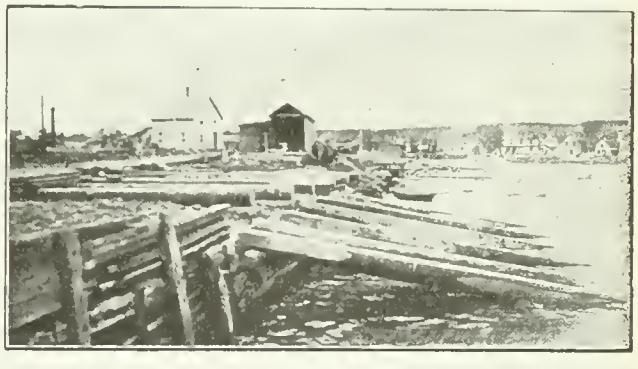

Fig. 3.—Launching Ways.

The water in this river is from thirty to forty-five feet or more in depth, and there is a tidal variation at Newcastle of about six feet, with a maximum of ten feet. The current varies with the tide from three miles per hour upstream on the flood tide to nearly six miles per hour downstream on the ebb tides.

The river bottom consists of fine sand and mud, twenty to thirty feet deep overlying harder strata of sand and clay, and sand and gravel, carrying artesian water. This bottom produced unusual foundation difficulties to contend with, there being no ledge rock on which to rest the piers, except at the Nelson abutment.

The design finally adopted for the bridge calls for four spans of 278 feet, and a draw span with an opening of 115 feet on either side of the draw. The approaches are each about 700 feet long and are composed of rock-

filled slope walls with an earth core, the rock fill protecting the earth from erosion by the waves and ice.

There are two abutments and five piers, each founded on piles, and built of concrete from the bottom to a point seven feet below mean tide. From this point to high tide level they are composed of cut granite masonry backed with concrete, and above high tide level of freestone backed with concrete.

Fig. 4.—Guide Frame for Caisson No. 1.

The abutments presented no unusual features. They were both built in open cofferdams, which were made by driving wooden sheet piling around a built-up framework of 12-in. by 12-in. yellow pine timbers, which formed the braces and wales of the cofferdam. As soon as the sheet piling was completed the cofferdams were pumped out and excavation made to ledge at a depth of twenty-eight feet at the Nelson abutment, and to a hard clay and sand strata at a depth of sixteen feet in the Newcastle abutment. The piles for the latter abutment were then driven with a drop hammer; using an extension lead pile driver; and the concrete of both abutments was placed in dry space.

The five piers presented the most interesting and difficult work. They vary from 56 feet to 69 feet in height and are being built in water from 35 to 48 feet deep.

The plan of construction adopted for these piers was the "Open Caisson Dredging Method." Caissons were framed up of yellow pine timber, twenty-six feet wide (except the pivot pier caisson) and of the height required for each pier. The two largest caissons were 63 feet 6 inches high. The pivot pier caisson was octagonal in shape, 42 feet across and 59 feet 6 inches high. The pivot pier caisson ready for launching is shown in Fig. 1.

All of the caissons were framed up on shore to a height of twelve feet around the first set of binder posts, which in the largest caissons were 31 feet high. The outside walls of this portion were built solid of 12-in. by 12-in. timbers and braced by one longitudinal and four lateral sets of timbers framed into the sides and bolted solidly at the intersections and to the binder posts. The bracing timber was placed in vertical rows so that the caissons were divided into ten pockets, four of which served later for dredging and six of them for loading with sand for sinking. The lower courses and part of the posts of one of the rectangular caissons is shown in Fig. 2.

The launchingways, illustrated in Fig. 3, were built of heavy timbers 30 feet long, laid horizontally and resting at their centre on a 12-in. by 12-in. rocker timber 54 feet long.

The caissons were built on these timbers in a level position and, when ready for launching, the caisson and supporting timbers were tilted on the rocker timber. This brought them in line with another set of timbers leading on the same slope into the water, and the caissons were launched by sliding on these timbers. No cradle or falsework was used and no difficulty was experienced with this method of launching. (Two hours were sufficient to tip and launch the caissons and thirty minutes after launching a caisson the launchingways were ready to start construction of the succeeding caisson).

Pontoons were secured in four of the pockets of each caisson before launching to float it in a level position when launched and hold it at an elevation in the water convenient for working. All of the caissons were lauched sideways as the water was only about six feet deep at high tide where the launchingways were constructed.

After launching, the caissons were tied up at a dock where building up continued until the caissons drew 23 feet of water, the total depth available, and then towed to their final site. They were then built up in place to their finished height, the caissons in every case drawing enough water to rest on bottom before being completed.

The strong current in both directions required special means of holding the caissons in place, the pressure against them being over 50,000 lbs. on the ebb tide at times. A guide frame composed of thirty-two piles, sixteen of which were batter piles, bolted to the other sixteen

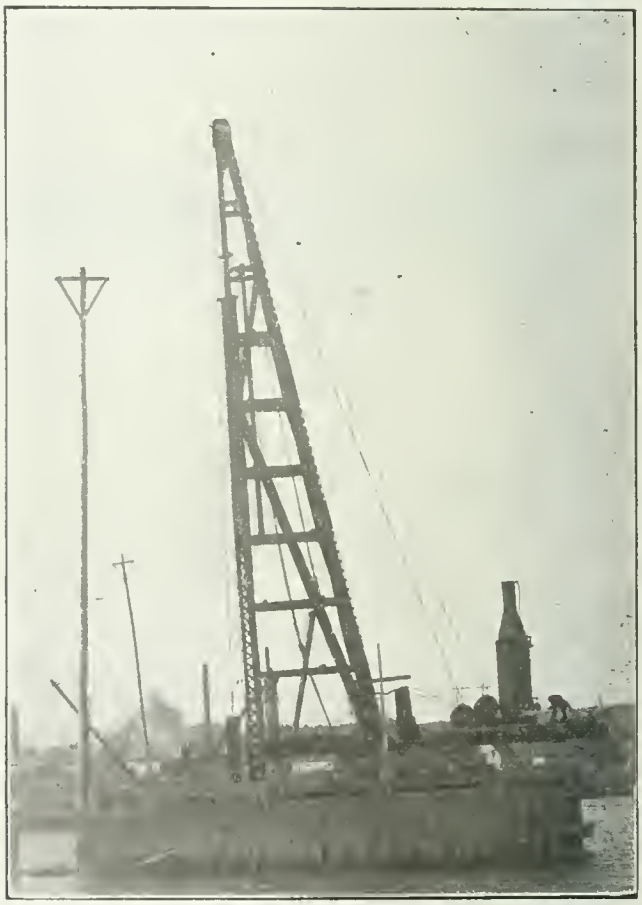

Fig. 5.—Pile Driver.

vertical piles, was driven to from three sides of a rectangle the upstream side being left open, as shown in Fig. 4. These piles were capped and braced in position. Chinese anchors, made by filling timber cribs 16 feet square with 40 tons of rock, were previously constructed and sunk about 400 feet upstream and downstream from the caissons. Each caisson was secured to four of these

anchors by means of 1 1/4-in. galvanized iron cables with double wire rope blocks and tackles so as to adjust it in position and hold it against the current.

The caissons were sunk through the mud and sand by dredging in four of the pockets with a clamshell bucket. False bottoms were placed in the other six pockets, sixteen feet above the cutting edge, and these pockets were weighted with sand while the dredging was going on. For one hundred years the Miramichi River has been a lumbering centre and many of the logs have become waterlogged and sunk. Many of these, sometimes twenty feet deep in the mud, were encountered in sinking the caissons, and were either taken out by the clamshell bucket or had to be cut off by a diver. High-power jets were also used by a diver under the cutting edge of one caisson to sink it through a strata of clay. In addition to the sand pocket method of weighting, pig iron was also used. All of the caissons have now been sunk and the maximum variation of any caisson is 15 ins. from the actual to the located centre line.

The hard strata of sand, clay and gravel on which the caissons rest might be sufficient support for the piers, but it was considered advisable not to rely on this, but to use a pile support. The heads of the piles had to be driven to a depth of over 60 feet below the top of the caissons in some cases. A sixty-five-foot extension lead pile driver was built and provided with a steel tube which worked in these leads. The piles were placed in this tube and driven by a 5,100-pound drop hammer working through the water. The piles were cut to length and driven until their heads were at the cut-off grade with a few exceptions. These were cut off by a diver. The pile driver was mounted on a turntable, the leads and engine turning on conical rollers on a circular track secured to a bed frame. A 2½-in. steel king bolt fastened the sills to the turntable. With this driver it was possible to reach every part of a caisson, while the weight of the driver, tube and hammer, amounting to over 25 tons, was supported along the centre line of the caisson. This pile driver is shown in Fig. 5. When the piles were driven in one caisson the pile driver was rolled on a scow and floated to the succeeding caisson.

After completing the pile driving, 12 feet of concrete was placed, entirely filling the bottom of the caissons. This concrete was put in with a bottom dump bucket working through the water. When the concrete had set the caissons were pumped out and the pier shafts constructed in dry space. Rail grillages were set vertically in the under-water concrete by a diver while the concrete was being placed and after pumping out, additional rails are connected to these by splice bars to reinforce the pier shafts. A view of the work four months after starting is shown in Fig. 6. The work was begun the latter part of May, 1913, and will be completed early in the coming winter.

The Hon. John Morrissy is Chief Commissioner of Public Works; A. R. Wetmore is Provincial Engineer, and A. R. Sprenger is Resident Engineer. The Foundation Company, Limited, are the contractors, and C. A. Wentworth is superintendent.

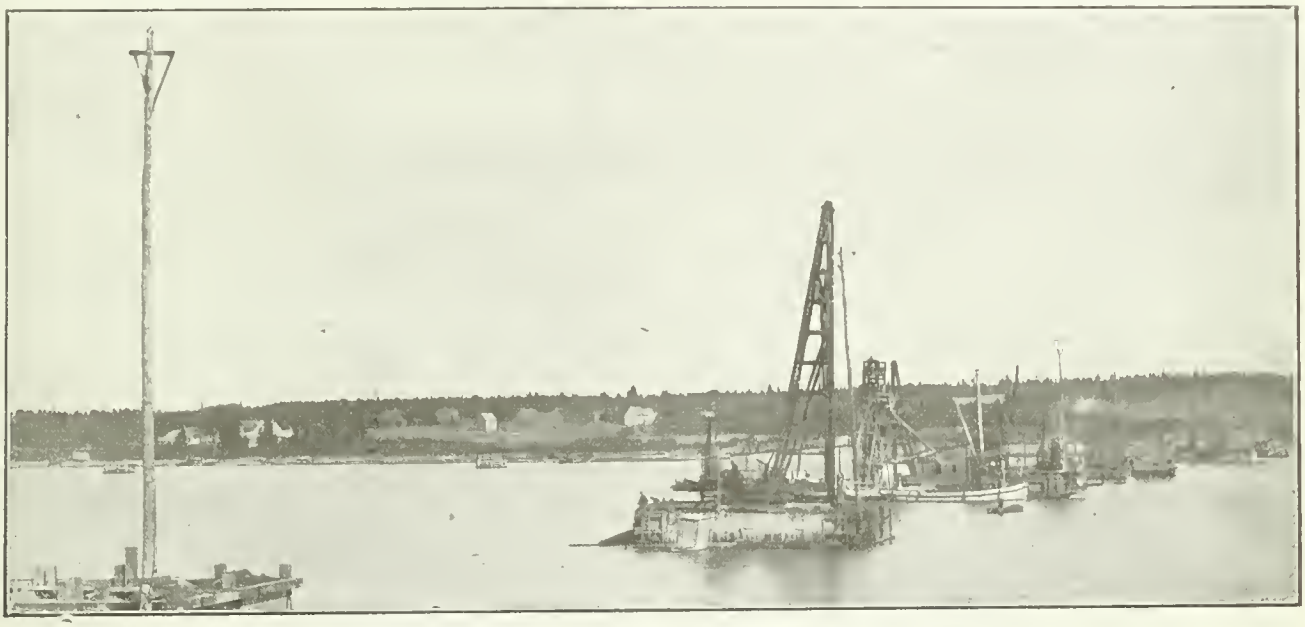

Fig. 6.—General View Four Months After Beginning Work.

The new harbor at Emden, Germany, which has taken three years to build, was opened recently with a good deal of ceremony. The sea sluice of the Emden harbor is the largest in the world; it is 260 meters long, 40 wide and 13 deep. Sixteen torpedo boats can pass through simultaneously within 15 minutes.

The Governor of New York, after consultation with the commissioner of highways, the attorney-general and the commissioner of efficiency and economy, has decided that hereafter asphalt shall be bought on open specifications and not under separate specifications for natural and oil asphalts, as was proposed by the consulting board of highway engineers. Full details have not yet been prepared, but it has been announced by the Governor that "it has been decided to have the specifications so drawn that every suitable asphalt known can be used, but to insert the conditions that every contractor must guarantee the road he builds for at least three, and possibly five years. This will do away with the asphalt scandal. This provision will give every asphalt dealer in the world who has an asphalt which he will guarantee for five years an equal chance with every other asphalt man for the business of New York State."

EFFECT OF HEAT TREATMENT ON THE STRENGTH AND DUCTILITY OF ELECTRIC FURNACE STEELS.

AN article written by T. R. Loudon, B.A.Sc., and descriptive of a Canadian electric steel furnace, appeared in October 23rd issue of *The Canadian Engineer*, and the general layout of the plant of the Moffat-Irving Steel Works, Limited, was included.

Since the appearance of the above article Mr. Loudon has conducted some experiments on the tensile strength of various carbon steels made in this furnace. The main idea followed out was to determine the strength of the steel as used in an ordinary steel casting, and then by heat treatment, to refine the grain size and note the effect on the strength and ductility.

The test bars were cast in rectangular form, and were then turned down to the standard shape for the tensile test of metal used in steel castings. Two such test pieces were made from each heat. One of these test bars was then placed in an annealing furnace and the grain size heat refined, care being taken to reach the desirable temperature for the various carbon contents.

The specimen bars were then tested in a Riehlé machine in the ordinary manner with the following results:

It is quite noticeable that in every case the tensile ultimate strength has been raised by heat refining the grain. The elastic limit, however, has been lowered but, as would be expected, the elongation results show a very great increase in ductility. The metal examined under the microscope shows evidence of being very sound, and, as intimated in the former article, the wearing qualities of this electric furnace steel are greater than mere physical tests would indicate.

		Natural specimen			Heat refined

ELEVATORS: THEIR USES AND ABUSES.*

By B. C. Van Emon.

AN elevator may be termed an ingenious mechanical device, invented and designed by man to overcome nature's imperative law, the law of gravitation. The overcoming of gravitation by the use of an elevator is by no means modern, for, many ages ago, history has shown that man had equipped a clumsy hand-power contrivance, whereby, with the use of considerable human energy, a greater weight was overcome by a lesser energy; but modern equipment, invention and devices place the elevator in a mechanical class entirely by itself. The towering buildings of modern construction, these massive structures of many stories, are rendered possible, practical and economically advantageous, only through the installation of the modern elevator, which, by its convenience in carrying passengers and freight to a higher or lower elevation and its accommodations for a practically unlimited number of passengers, increases property a hundredfold in its initial value.

Like most modern inventions, which many centuries ago were in crude construction, the completion and almost perfection of the elevator has been an achievement left for the present century. Thus, again, like the perfection of all other wonders which now seem to us so commonplace, the practical completion of the elevator has been a matter of slow evolution.

The combined mechanical genius of many elevator engineers has given to the public various types of elevator construction, of which a list is herewith presented:

Elevators may be divided into the following classes: Handpower elevators; belt or power-driven elevators; steam elevators; hydraulic elevators; pneumatic elevators; electric elevators; each of these being divided into classes by governing conditions.

Handpower Elevator.—This is the oldest elevator known, patented in the year 1846. When used for handling freight in buildings the machinery is generally located overhead and consists of a long wooden drum, with a large gear wheel attached to the end; this wheel engages with a smaller pinion driven by a large "bull" wheel, or wheel upon which a rope is placed, leading from the lower floor through the several floors of the building over this "bull" wheel; this rope is spliced and is made continuous. By pulling this rope the countershaft is made to revolve and drives the small pinion; this engages the large gear wheel which turns the drum upon which the rope is attached to the car, and in this manner lifts the freight. The sizes of these hand-power elevators, under this condition, vary, according to the work to be done, and are built for capacities of 4,000-pound or 5,000-pound loads at a very slow speed.

The next type of hand-power elevator commonly used is for sidewalk elevators, this type dating from 1858. The gearing or hoisting mechanism is generally built on an iron frame, and consists of gear wheels, ratchets and brakes. These frames are sometimes built of wood, with

*Read before the Technical Society of the Pacific Coast, July 18, 1913.

the gearing mounted as upon the iron frames, and are used for raising and lowering merchandise from basement to sidewalk level.

Double Belt Worm-Gear Elevator.—Another type of elevator commonly used for handling freight, is driven with belts from the main line shaft in the building to pulleys on the worm shaft of the belt elevator. These are double belted, one belt traveling in one direction, the other, a cross belt, traveling in the opposite direction; and by the use of a pull rope placed conveniently in the well hole, by means of a mechanical device, these belts are shifted on and off the tight pulley on the worm shaft, giving the operator control of the direction of the elevator. When the rope is pulled to the neutral position, the belts are both off of the tight pulley and run on the loose ones. This same movement sets the brake on the tight pulleys and holds the car when fully loaded. The worm gear mechanism is enclosed in a cast-iron casing and filled with oil, and on the worm wheel shaft is placed a winding drum of sufficient size to accommodate the hoisting cables, these cables being carried up through the hatchway over a sheave on top of the elevator shaft, and down to the car. On the opposite side of the drum are ropes passing upward through the building over another set of sheaves, that are attached to a counterweight, balancing the car and part of the load, this arrangement giving the best results. These worm-gear machines were built in sizes as high as 6,000-pound loads and were considered very large elevators in the early elevator days. However, even with the great advancement made in the elevator industry, a belt elevator is rarely built to exceed a capacity of 6,000 pounds even at the present day.

Later, the belt elevator was operated by an electric motor with a single belt running to the drive pulley, or tight pulley on the worm shaft. This electric motor was started and stopped by an electric switch which reversed the current in the motor, and gave it the direction required, thus eliminating one belt and giving a direct drive from the motor power to the elevator, and when the elevator was not in operation no power was being consumed. This was practically the next step in the elevator advancement.

Steam-Driven Elevator.—About the period these belt-driven elevators were first used, there was also a steam-driven elevator, operated by steam direct to an engine, of the reversing type, somewhat like the "Brotherhood engine" used on steamboats to control the rudder. These steam-driven elevators were operated by a pull rope with a pilot valve on the engine almost in the same manner in which the steamboat operated its controlling mechanism with the rudders. The first of these engines were direct-geared to a drum, with suitable rope connections over sheaves overhead to the car and counterweights. Latterly, these steam engines were geared to worm-geared machines.

Hydraulic Elevator.—This elevator was developed about this time, and consists of a large cylinder with a piston and a piston rod running through a stuffing box properly packed, and on the end of the piston rod are fastened several wire ropes wound around a very small drum, securely fastened to a shaft, upon which is keyed a very large drum. This was what was termed, at that time, a "pull-back machine," and was run generally from the city water pressure or city hydrants. This was controlled by hydraulic valves for admitting water into the cylinder, and also discharging it into sewers. These elevators were quite commonly used about 1880 and 1890, at which time the electric elevator came into general use.

Plunger or Hydraulic Ram Elevator.—About 1882, the first plunger or hydraulic ram elevator, as it is termed, came into use. This plunger elevator consists of a piece of steel or iron pipe, which is turned true and smooth on the outside and operated through a stuffing box, which is securely fastened to the top of a piece of pipe of a larger diameter in which the smaller is enclosed. By admitting water on the top end of the larger pipe, in which the smaller pipe is placed, the water pressure will cause the smaller pipe to pass through the stuffing box and propel the car in either direction when the control valve is opened, thus allowing the water to escape into the sewer. Plunger or ram elevators are set into the ground, a hole being bored of sufficient size and depth according to the travel and height of the building in which the elevator is to be operated.

At the present time, plunger elevators are built for almost any travel up to 300 or 400 ft., and the water pressure applied is in ratio to the height of the building; in some instances, the water pressure required being 700 pounds per sq. in., varying, of course, according to the size of the ram and the conditions under which it operates. The writer will not enter into technicalities to the extent of figuring out accurately just what the strains are, and what the tension on the ram would be, under certain conditions, but it is a well-known fact that in tall buildings where the ram or plunger elevators are used, when the ram or plunger is a certain distance out of the stuffing box it comes under a pull instead of a push, and, in many cases, and almost universally in high buildings, it is necessary for the manufacturer to put a couple of wire ropes inside of the ram or plunger pipe the full distance, these being securely fastened at both ends very taut to hold the compression of the ram, so that when the stress or pull is put on the car after reaching a certain height it will not separate or pull apart at the joints, these joints being necessary in the plunger to keep it water-tight, and also assist in overcoming the strain which is placed on the pipe. This, it will be readily understood, becomes a strain or pull on the plunger after it has reached a certain distance from the ground or level at which the stuffing box is placed, caused by the increasing counterweight, this being necessary to overcome weight of the car and plunger, the same being generally made of steel pipe of a thickness sufficient to withstand the water pressure admitted in the larger pipe, around which the water is encased, which presses against the smaller or finished turned plunger which travels up and down the well hole. The plunger elevator is now being very successfully operated in tall buildings; the only drawback being the immense weight which constitutes the elevator equipment, also the time element necessary in starting, stopping and reversing this enormous weight in a given time. The stress upon the ram or plunger pipe, casing, control valves and other parts, is very great, as the water pressure is very high. An elevator equipment in a building of 300 ft. travel consists of the ram or plunger, the car with its counterweights, necessary to properly balance the car, and plunger which must be very heavy; and it seems to the writer that the time element is very necessary in starting, stopping, and reversing this elevator; whereas an electric elevator made very light can be started, stopped and reversed much quicker, and, unquestionably, can run at any speed desired.

Admitting the plunger elevator for tall buildings to be very expensive, it being necessary to bore a hole in the ground equal to, if not a little more than, the total

height of the travel of the car, it is a fact that the turning of the steel plunger or ram, the fitting together of the same, with the outside casing necessary to contain the high water pressure, the stuffing box at the top of the outside casing, with all its pumping apparatus and controlling apparatus, the necessary variable counterweights and all their accessories, must entail more expense than any direct electric elevator. Conceding that the starting and stopping of the Hydraulic elevator are much easier and more gradual, the actual running conditions of both are the same, and, so far as safety is concerned, the electric elevator is conceded by experts to be safer than the plunger type. In high buildings the electric elevator requires less for repairs, is less expensive to operate and costs less for installation.

The efficiency of the plunger elevator depends entirely upon its construction, and to make it efficient it is necessary to properly counterweight the same, so that as the plunger leaves the ground floor, and it comes out of its stuffing box, it pushes the car up; the counterweight in coming down must be so constructed that it will increase in weight equal to the same amount of the weight of the plunger coming out of the stuffing box. For example, suppose one foot of plunger should weigh 25 lb., every foot of counterweight that passes over the overhead sheave must weigh an equal amount, and it is readily understood that in tall buildings when the elevator reaches a certain point in its travel it becomes a pull upon the ram by the amount of counterweight that has passed over the sheave, and that the remaining part of the ram from this point in the shaft down to the stuffing box is holding back to this point over the counterweight, so that as the elevator ascends beyond this given point there becomes a strain upon the ram instead of a push. As before stated, to insure safety there must extend the whole length of the ram, and on the inside, a wire rope drawn very taut to make sure that the ram will not separate at one of the joints and allow the elevator car with its load to go crashing through the roof, which actually occurred with fatal results in an eastern city some years ago.

In the use of safety devices for the car it is necessary to have them so arranged that they will operate in either direction, because the safety devices must work in the reverse direction after the ram is placed under a strain by being out of the casing a certain required distance.

There is also another type of plunger elevator where the plunger is not placed in the ground, but is at one side of the well hole. This type is worked under somewhat the same conditions heretofore mentioned. In this type of plunger elevator, the weight of the plunger must equal the car plus the load. This plunger is held up by the pressure of the water, and when the load is lifted, the pressure of the water is released from the cylinder under this plunger, thus allowing the water to escape, and the excessive weight of the plunger over the weight of the car through its multiplication of ropes and sheaves will lift the car. When the car descends, it is necessary to produce a pressure in the cylinder great enough to lift this ram or plunger and allow the car to descend. Ordinarily, this type of elevator was a multiplication of "two to one" or "three to one" in the rope connections, and all of the work is accomplished through wire ropes connected to the car, over sheaves, placed overhead in the hatch. This type of elevator has the reverse features of the plunger elevator when the plunger elevator is a certain distance out of the ground, that is, the safety devices on this elevator operate in the opposite direction to those on an ordinary electric elevator, for if the cylinder which holds the water should break or a pipe should give way, allowing the water to discharge freely from the cylinder, the plunger would drop very rapidly, and the elevator would attain excessive speed in going up, and might result in an accident. These safety devices must operate in case the ropes should break, and prevent the car from falling, and they must be operative in both directions.

This type of elevator is very successfully operated at high speeds, can be started and stopped very quickly, and comes nearer the action of a direct electric elevator for high buildings than any other hydraulic elevator.

Horizontal Multiple-Sheave Elevator.—This type is generally placed in the basement of a building on the floor and consists of a large cylinder with a piston, a connecting rod and a set of multiple sheaves travelling on a crosshead mounted on a track. On the other end of the cylinder is also placed a set of sheaves, equal to the number which travel with the piston and connecting rod, and as the water is admitted into the cylinder between the head and the plunger it moves the plunger out, thus pushing the plunger and sheaves upon the ropes passing around these sheaves—the other end of these ropes being attached to the cylinder—and thus lifts the car. In this type of elevator, the car is counterweighted to within a point wherein the weight of the car will overcome the water in the cylinder, and when the valve is open to lower the car the weight of the car must be sufficient to push the water out of the cylinder into the tank where it is again pumped under pressure. This latter is the most universal type of hydraulic elevator used for passenger service in high-class buildings, as the starting and stopping of this elevator is very gradual and accomplished without shock or jar, and it may be handled successfully at very high speeds.

Direct-Connected Electric Elevators.—There are several types of direct-connected electric elevators, one consisting of the worm gear with drums attached and ropes fastened to the winding drums; another, the direct-connected worm-gear elevators with traction sheaves around which the rope is passed several times and run over an idler sheave, where one end of the rope is fastened to a counterweight, and the other end to the car. This worm-gear traction elevator is now coming into general use.

Another type of traction elevator is the "one to one" type, with the traction sheave securely fastened to the rotating shaft of the armature and the idler sheave directly over or underneath same, depending upon the position and condition under which the elevator is to operate. The ropes pass around these sheaves the same as in the worm-gear traction type of elevator. This type of elevator is capable of an unlimited speed, while the worm-gear traction drive elevator is somewhat limited in speed.

Again referring to the worm-gear elevators with their winding drums and ropes securely fastened thereto, it should be said that they are generally made in two types, one of a single worm and worm wheel, and the other, a double worm and two worm wheels.

The double-worm machines consist essentially of two worms in an oil-tight casing, one of which is made right hand, the other left hand. The two worm wheels in which these worms engage are made right and left hand to fit, and they are so arranged that, in most cases, the two worm wheels constitute a gear wheel, as well as a worm wheel, being meshed together, thus constituting a three-point connection between the right-hand worm and the

left-hand worm and the two worm wheels which are gear wheels, thus giving the double-worm elevator its superior working qualities and strength over the single worm, because it has double the amount of contact or wearing surface between the worm and the wheel, thus allowing the use of a much larger motor and doing much heavier duty than can be done with a single worm, since there is a limit to the amount of work that a worm will do under a given load and speed. This double-worm elevator, or tandem worn-gear elevator (as it is commonly known), is only used for high-duty purposes, that is, where it is high speed with ordinary heavy loads for passenger service.

In some instances these worms are cut a double pitch, these being two worms of the right hand and two worms of the left hand, thus giving what is termed four points of contact for driving the worm wheel upon which is fastened the winding drum, around which the cables are wound. These worms are always made of a very high grade of steel, and the worm wheel also is made of the best grade of phosphor bronze, thus giving the best metals known for heavy friction at high speeds. These worms are operated, in some cases, up as high as 1,400 rev. per min. and are giving excellent service at that speed. They are all enclosed in an oil bath with a special oil for the purpose, and when doing very heavy duty become quite warm at times.

With all of the worm-gear elevators it is generally conceded that, if properly constructed, the efficiency is about 50 per cent., and in instances less than that; so that in placing the electric motor for an elevator of a given duty, it is necessary to put on a motor having a capacity not less than 50 per cent. greater than the theoretical work to be performed, and in many cases as much as 75 per cent. greater capacity. It is also necessary to have a motor which will do at least 50 per cent. excess duty for a few moments in starting the load and getting under headway in a given time. It is now the rule for manufacturers of motors for elevator purposes, to build them for what is termed "intermittent duty," so that they will stand an excessive over-load for a few moments and also operate at their normal horse-power and carry the load for the time required. These motors are now built especially for this purpose with large extra shafts, extra strong windings, and other features necessary to meet the severe conditions under which an elevator motor is to operate.

Controlling devices for these motors are also built by manufacturers who make a specialty of that class of work, and who have made an exhaustive study of the duties required for controlling apparatus. The advance made in the last few years in such apparatus is very marked, as the elevator controllers at the present time are much more durable than in former years, are simpler, more efficient, less liable to breakage and are somewhat cheaper, owing to the large number now being built.

There has also been developed within the past few years the full magnet control for alternating-current elevators. These controllers are built in all sizes.

The difficulty in the past has been that the laminations for the working parts of the solenoids or the magnets required to operate the switches have made too much noise, and in operation would heat, and the constant expansion and contraction of the laminated parts loosened them and broke them down completely. But these A.C. solenoids and magnets are now so constructed that they do not heat and the noise is at a minimum, thus giving excellent service in operating the switches. No doubt in time there will be a marked improvement in the A.C. controlling mechanism for elevators. They are also well developed for the full automatic control elevators such as are used in apartment houses, and their cost is but very little more than for the D.C. apparatus to do the same duty.

During the past few years the A.C. motor for freight purposes has made marked progress and is giving good service without interruption.

Within the last year or so an A.C. motor has been introduced for elevator purposes which can be thrown directly across the line using a reversible switch. These motors are very simple. They have an enormous starting torque, from two to three times their normal running torque with about the same overload of current necessary to produce this torque. This makes the A.C. motor very valuable for small freight elevators. These motors are now built so that they run very quietly and are very flexible in starting.

In the larger motors, for heavy freight duty and also for passenger service, what is termed the "slip ring armature resistance type motor" is used, operating with practically the same device that operates a direct-current motor, and the resistance in the armature is cut out in several steps by a control magnet, operating cut-out contacts, for cutting out or short-circuiting the armature resistance as the motor comes up to speed, thus giving it from two to three times its starting torque and holding the same until the armature resistance is completely cut out. This development in the A.C. motor has been very beneficial to the elevator manufacturer, since prevailing current supply is now alternating, and it is only a question of time when the direct current will become obsolete.

The first electric motors for power came into use in 1886 and 1887. These electric motors were operated from the old constant-current arc-light machines, viz., 9.6 amperes of constant current where the voltage varied according to the load placed upon the electric motor. These motors were controlled by shifting the brushes on the commutator, and were, at that time, the only known electric power which gave commercial satisfaction. A great many of these motors were built in San Francisco from 1886 to 1890. The old constant-current motors were built up to 15 h.p. and as high as 20 h.p., this latter being considered a large motor. They were belted to countershafts for driving pumps for pumping water into a tank on the roof, or in a steel compression tank under air pressure, where the water under pressure was used to operate the elevator, it being discharged from the elevator into a surge tank and then repumped under the pressure required to operate the elevator.

About 1890 appeared the constant potential motor which is now in use, that is where the voltage is kept constant and the amperes vary according to the work to be done, and wherein the motor does not require a governor to operate the brushes to control the speed, but where the brushes of the motor are fixed, the speed depending upon the adjustable relations. These motors were much cheaper than the old constant-current motor and gave better results. About this time all of the controlling devices necessary to start and stop the electric motor which operated the pump were also perfected. Some of the apparatus is in use at the present time, giving fairly good service.

In 1891, the writer patented a direct connected electric elevator. This was a tandem-geared, or double-worm machine with a right- and left-hand worm and a right- and left-hand worm wheel. This worm wheel consisted

of two gear wheels spirally cut on about the angle and pitch of the worm, and the worm wheel was hobbed out of the centre sufficiently to make a proper contact between the worm and the worm wheel. These worm wheels were made of common cast iron accurately machined, and the right- and left-hand worms were made of phosphor bronze securely keyed to the worm shaft. Upon the end of the worm shaft an electric motor was installed, designed and built by the writer. Also all of the controlling mechanism was operated mechanically by reversing switches with springs, lever and dash pot which cut out the armature resistance as the motor came up to speed. This elevator was sold to the Keil estate and placed in their building at 770 Mission Street, occupied by Hulse-Bradford Company. The elevator did good service up to the time of the great fire of 1906.

About this time the writer patented a larger elevator of this same type, the motor and control however being of a different type from the above. This elevator was placed in the Old Cliff House about 1892 and did good service until it was destroyed by fire. This installation was first operated from 110-volt circuit of direct current, and was later changed or rewound for a 220-volt circuit. When the electric railway was built to the Cliff House, it was changed to 500 volts.

The single-worm elevator was then developed by the writer, who later patented several devices for controlling elevators, and after much study and experience these devices were brought up to satisfactory efficiency.

Since 1900 the development in electrically controlled elevators has been very marked, and the writer predicts that the advancement in the next thirteen years will be equally as great.

About 1898 or 1900, the eastern manufacturers realized the importance of the demand for electric motors and electric controllers for elevator purposes, and they made a study in detail of elevator equipment, viz., the making of motors especially for this purpose, also a controlling apparatus made for controlling freight and passenger elevators electrically driven. The constant usage of these motors and controllers has exposed their weaker points, and they have now reached a point of efficiency where they are commercially a great success, also being economical and practical in their operation.

Within the last few years, in the electric motor especially, there has developed what we term the "interpole motor," which has eliminated the commutator trouble originally had with reversible motors under heavy duty with varying loads.

The writer wishes to state a few facts regarding the care, maintenance and abuses of elevators. We are aware of the many advantages to be gained by good elevator service in buildings equipped with the modern elevators of the present day.

Good Service.—It is not enough that the owners get from the manufacturers a first-class machine; they must do their part, employing good, reliable, intelligent men, who are capable of understanding the importance of keeping all parts well cleaned and properly oiled, and who understand making adjustments when required, thus in many instances lessening the liability of accidents and reducing the up-keep of the machinery very materially; and the writer would ask the consideration of owners and the public for the elevator manufacturer. who is the man who is blamed for all the mishaps, accidents and unsatisfactory results, while as a matter of fact these conditions in many instances are caused by lack of care and attention on the part of the owner or, more often, the tenant. Then again, many troubles can be traced to the architects or engineers, who, when planning the buildings, fail to make the proper allowance of space for elevators; also, conditions are many times disadvantageous, such as poor light, etc.; and many other conditions obtain, all detrimental to a successful installation of what is conceded to be a most complicated mechanical contrivance.

In many instances, the owners of buildings consider their responsibility ended with the payment of the manufacturer's bill, forgetting that only by eternal viligance and care can any machinery give good service; elevators are certainly no exception to this rule.

An elevator doing heavy duty in a building is a very essential part of the building, and when the elevator is out of commission the expenses of the building are just as great, without any results. Owners should realize that elevators should be taken care of by men experienced in elevator mechanism.

The writer will give the following illustration to make his meaning plain. Not long ago he was called to a rooming house to figure on putting in a new commutator on a motor which had been running for several years. The motor and controlling devices were placed under a stairway leading from a back entrance into a basement; part of the elevator machinery being in one room, a partition under the stairway brought part of it in another room. The controlling devices were so close to the wall as to render it absolutely impossible to reach one side at all. In this room were four barrels full of inflammable matter, one of which was placed directly against part of the controller. It would have been easy for a spark from the controller to have dropped into this barrel. Undoubtedly this would have set fire to it, thus endangering the whole building. Around the machinery, the oil was ½ in. thick. Old rags, boards and shavings covered the floor. This elevator was in the care of a Japanese, who could neither speak nor understand English, consequently it was impossible to make him comprehend that the elevator must be kept clean. Doubtless these conditions exist in many other cases in this city.

The writer suggests that, when owners and architects of buildings decide upon the elevator equipment required to meet the conditions under which the building is being built, it would facilitate matters to employ an elevator expert, who as an expert should be qualified to give them information valuable to insure good results, inasmuch as it is very material that the elevator manufacturer should understand the details, viz., how many entrances there are to the car, how the overhead supports should be constructed, what room and provisions are to be made for the semi-automatic gates, whether or not a freight elevator is required, and also the conditions required for fire hoods and fire doors, and much other necessary information. All of this is required to make a successful installation, and conduces to the owner's benefit, insures satisfactory results to the lesee of the building, and last, but not least, is of great assistance to the elevator manufacturer in helping him to thoroughly understand just what is required.

You will understand that the elevator contractor, in bidding upon the installation of an elevator, in most instances only receives a few of the actual conditions under which the elevator must give service, such as the load, speed, travel and size of car, etc. This is only a part of the information he should have. In order to bid intelligently, he should know every gate, fire door, and many other conditions with which he should be thoroughly in touch in order to insure a good installation.

The writer knows of several instances where the architect has designed a concrete well-hole, or a brick well-hole, without any recesses on the inside for gates; these shafts, being constructed for fireproof purposes, must necessarily have a roller drop fire door on the outside, this door completely covering the entrance. The gates must be put outside in the room beyond this roller door and the contractor is obliged to drill through the walls to put connections through, so as automatically to trip the the gate when the car leaves the floor. Gates installed this way are invariably unsatisfactory. The writer suggests that when architects or engineers require bids for elevators it would be advisable to have a complete drawing made of gates, doors, automatic locks, safety devices and other things necessary, so that it may be determined how they should go into the elevator installation, these drawings accompanying the specifications of the material to be used. Then the bidder has full knowledge of what is required and is able to bid intelligently, while without this knowledge the elevator contractor is compelled to use his own judgment, and in many instances it is at variance with the ideas of the architect and owner and often leads to confusion and dissatisfaction to all parties concerned. Hence, the writer's reason for suggesting the services of a competent elevator engineer to make the lay-outs and specifications for the bidder.

A good, efficient elevator installation is of vital importance to all concerned in the elevator equipment of a building, and in order to obtain this the architect and contractor must work together to this end and for their mutual advantage, the architect giving the contractor all necessary data, etc., and the contractor, upon the other hand, assisting the architect by giving him the benefit of the knowledge of actual experience.

SASKATOON'S WATER AND DISTRIBUTION SYSTEM.

OWING to the expenditure of much money and effort on the Saskatoon water supply and distribution system, a deficit of $23,802.01, shown last year, has been converted into a considerable profit. This has been effected by rigid economy and extensive repairs and reconstruction. Some of the improvements carried out at the pumping house during the year were the removal of 3 return tubular boilers and of the brick chimney; the remodelling of the old boiler room and the division of the same into two; the utilizing of the space previously occupied by the boilers for the generator room; the rearrangement of the entire steam piping and the erection of two new feed water lines, one from the injector to the boilers, and the other from the feed pump to the boilers; the transference of a 500 k.w. reciprocating unit from the power house, and its erection in the pumping plant, together with the exciter, the condenser, and the air pump; the complete rearrangement of the steam and exhaust steam piping, and the placing of the same beneath the floor in the steam pump room. Other changes in the building itself are the raising of the roof 5 feet and the making of it fireproof; the placing of a new concrete floor in the pump well; and the removal of two 100-h.p. domestic pumps and one 50-h.p. booster pump from the steam pump room to permanent positions in the new pump room, and the connection of the delivery pipes made to the city mains.

This rearrangement of the pumping plant has been undertaken, with the result that the city can now pump its entire water supply with electrically driven centrifugal pumps. The present capacity of the pumps is 4,000,000 gallons per day with a nominal pressure of 60 pounds in the mains. In case of fire the pressure can be instantly raised by means of a booster pump to 100 pounds. The capacity of the pumps is sufficient to meet present demands, the average daily consumption being about 1,800,000 gallons. Provision has been made so that additional pumps can be added without enlarging the building, which would provide a daily supply of 12,000,000 gallons, sufficient for a city of 180,000 population, on the present basis.

The filtration plant has caused the least concern on the part of this year's council, having given almost complete satisfaction.

Further improvement is arranged for, in order to eliminate complaints made last winter with reference to the delivery of water to householders who are not supplied from the city mains. Small vertical boilers will be installed at several standpipe stations for heating the water and thawing out the delivery tanks. This will effect a saving of $20 a month for the city on each standpipe.

The economic effect of the works carried out at the pumping plant is shown by the following figures: in May the output was 59,119,060 gallons and the operating cost was $6,079.10, or 10.28 cents per 1,000 gallons; in October the output was 51,556,000 gallons and the operating cost was $3,686.79, or 7.15 cents per 1,000 gallons; showing a decrease of 30.4 per cent.

The waterworks department proposes, however, by carrying out further improvements to acquire still greater gain for the city, and anticipates a surplus in 1914 of $10,000. This will be chiefly effected by the reduction in the cost of fuel, which will result from the doing away with the stand-by at the pumping station in case of breakdown—e.g., the keeping up of steam on one of the boilers, which is prepared at any time to propel a reciprocating engine, drive a generator, and run horizontal steam pumps,— and the substitution of a separate stand-by and the installation of a duplicate main from the power house to the pumping station. This, alone, it is expected will decrease by $14,000 a year the waterworks expenditure.

That sawdust and other mill waste can be profitably manufactured into briquettes for fuel is evident from the fact that a large lumber company in British Columbia is erecting a $50,000 plant, which will have a daily output of about 30 tons of such briquettes. They will sell for about five dollars a ton at the mill.

The quantity of coal required to produce a ton of coke is much less than was required formerly. The average gain in 1912 compared with ten years ago is probably at least 160 pounds. It is doubtful if in the earlier years the actual yield of coal in coke exceeded 60 per cent., whereas in 1912 it was 67 per cent., according to the United States Geological Survey. This gain is largely due to the increase in the production of by-product coke, in which the yield of coke from a ton of coal is very much higher than in making beehive coke. In Illinois, Indiana, Massachusetts, Michigan, New Jersey, New York and Wisconsin, where coke is made exclusively in by-product plants, the yield varies from 69.6 per cent. in Wisconsin to 81.8 per cent. in Indiana, whereas in the States where beehive practice prevails the yield in 1912 varied from 50 per cent. in Georgia to 66.5 per cent. in Pennsylvania.

PROTRACTING RAILWAY TRAVERSES BY THE METHOD OF CO-ORDINATES.

By J. A. Macdonald, Ottawa, Ont.

IT has been repeatedly shown by various writers, that when the distance measured on a sphere is a portion of a rhumb line, whether direct or oblique, or when it coincides with a parallel of latitude, when it crosses a meridian obliquely, and forms equal angles with them, all the corresponding amounts of latitude and departure, and the distance itself, may be accurately represented by the three sides of a right-angled triangle. As the length of lines to which we apply latitudes and departures are, when compared with the vast length of a great circle of the earth, extremely small, the error arising from considering the distances measured, and the difference of latitude and departure corresponding thereto as three sides of a right-angled triangle, is trifling.

A Knowledge of Plane Trigonometry Required.—Such surveys as are conducted under the rules of plane trigonometry may be all classed as having for their object either to obtain an accurate plan of a limited portion of country with a view to the calculation of its area, or its suitability for a railroad, by obtaining representations of the varying features of the surface, such as the extent of mountains, woods, lakes, rivers, roads, towns, villages, coast lines, or any other details of country through which it may be required to run a railroad.

An acquaintance with the higher branches of mathematics is necessary for those who are entrusted with surveys of any kind, railway and otherwise, though a wonderful degree of perfection is frequently obtained by practice and with only a limited knowledge of the rules of plane trigonometry. It is for the assistance of the labors of those so equipped that the following notes may be applied in practice, assuming that the reader is acquainted with the use of the transit or the surveyor's compass, and the chain.

Mapping of a Railway Line.—The method of plotting the survey of a line of road, or mapping by traverse, is a *modified application of protraction by co-ordinates*, for in a road survey the lines generally lie on one side of the meridian, though not necessarily so. Table I. contains an extract from a survey, by the writer, of a line of road in the North-West provinces, made in the year 1906, and will serve to illustrate the application to this method. The second column refers to the angles of deflection taken with the transit; the third, to the true bearings, either astronomical or magnetic, as calculated from the deflection angles, registered on the limb of the transit, and so on.

Fig. I. (sketch-plan) contains a few of the first stations protracted on a definite scale. The stations are plotted in the following manner: Draw any line (Fig. I.) to represent the meridian, and assume any point upon the line for the first station of the survey; mark a point upon the meridian, "O." The position of this meridian on the plan, and of this first station, will depend upon the general direction of the line to be surveyed.

Station.	Def. Angle.	Bearing.	Distance.	Lat. N.	Lat. S.	Dep. E.	Dep. W.	Total Lat.	Total Dep.	Offsets.
0	31° 40′	N. 25° 30′ E.	1910	1724	....	822	....	0	0	
1	73° 20′	N. 47° 50′ W.	910	612	....	....	674	1724	822	
2	61° 15′	N. 13° 25′ E.	1420	1381	....	329	....	2336	148	
3	47° 00′	N. 60° 25′ E.	2000	987	....	1739	....	3717	477	
4	21° 10′	N. 39° 15′ E.	1500	1161	....	949	....	4704	2216	
5	40° 00′	N. 0° 45′ W.	1420	1419	....	....	18.6	5865	3165	
6	43° 30′	N. 42° 45′ E.	1205	875	....	818	....	7284	3146	
						4657	692.6	8159	3964	
						692.6 subt.				
Totals				8159		3964				

The first station being marked "O," or 0 + 00, where the transit was first set up, and the bearings having been taken from the back-sight of a connecting line, N. 57° 10′ E., the instrument is then put in the meridian

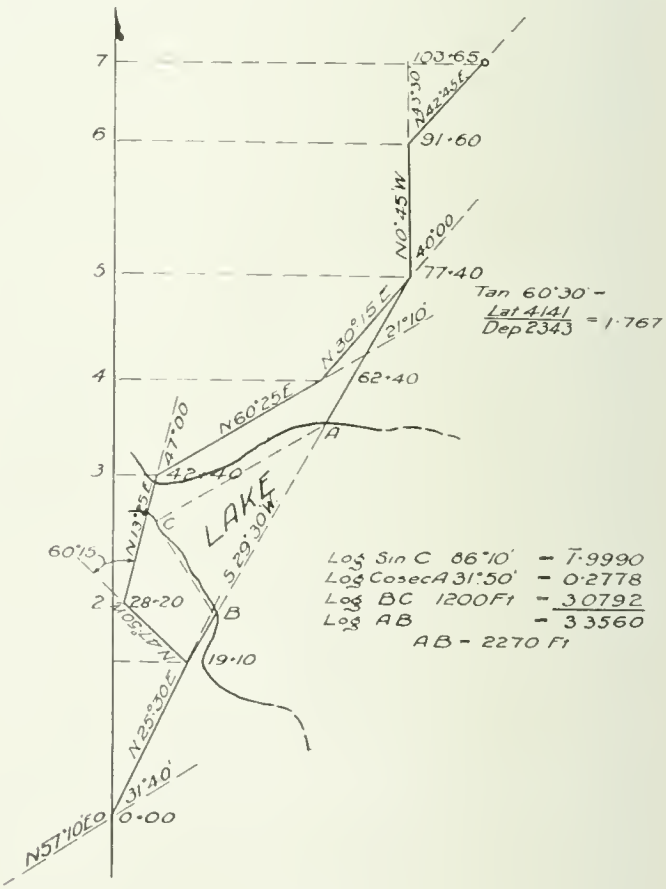

Fig. 1.

by turning 57° 10′ back to zero, with a suitable scale. Mark a point N. from Station 0, 1,724 ft., being the first entry, and opposite to the number 1 in the plotting column, Total Latitude, of the table, and number the point 1′. From 1′ on a line perpendicular to the meridian

mark a point 822 ft., being the first entry, and also opposite to the number 1 in the plotting column, Total Departures (10th column), and this point will be Station 1 (19 + 10). Again, from Station 0 in a direction N. 2,342 ft. mark a point and number it 2′, and from 2′ on a line perpendicular to the meridian set up the point E. of the meridian 148 ft., which will be Station 2 (28 + 20). Proceed in a similar manner for the remaining stations, taking all the values successively from the plotting columns, under the head of Total Latitude and Total Departures (9th and 10th cols.), and laying them off as above from Station 0. Draw lines connecting the stations 0, 1, 2, 3, etc., which will represent the measured or station lines of the survey, from which distant objects are filled in by intersection, and near ones by offsets in the usual way.

By the use of a parallel ruler (a pair of set-squares answers quite as well) all the points of a series may be defined at once. When the scale is laid along the meridian all the points, 1′, 2′, 3′, 4′, 5′ 6′, etc., may be pricked off at once from the figures opposite to these numbers in the 9th column of the table. For the Departures (next column) it will be necessary to draw a line, precisely perpendicular to the meridian at Station 0, then with the parallel ruler draw lines parallel to the first one through the latitude points, 1′, 2′, 3′, etc. Now, place the scale on those several perpendiculars and measure the departures (column 10) opposite to their numbers, and make a fine point. These points are then connected by lines joining each, and represent the distances between stations. It will be seen that the column distance is not used in plotting. This column is only used to obtain the latitudes and departures of the several courses.

In protracting each piece of work it will be found advantageous to fix the extreme points first before filling in the intermediates. Great facility is also afforded thus for reducing, enlarging, or transferring maps of single lines of road where the bearing of the line is considerable. The differences of latitudes and departures in the columns entered against the several stations serve to determine the relative geographical position of those stations with reference to the first, or any other station in the series.

Obtaining a True Bearing.—The lake shown in the plan was first crossed at its narrow part, involving several sharp curves. It was thought that the lake might be boldly crossed in as nearly as possible a direct line at Station 5, 77 + 40. It was decided to back-run a line, directly across the lake to Station 1, 19 + 10, to strike this station as nearly as possible.

The latitude and departure from 19 + 10 (Station 1) to 77 + 40 (Station 5) is found as in Table II. :—

	Lat.	Dep.
Station (1)	0	0
" (2)	+ 612	— 674
" (3)	+ 1933	— 345
" (4)	+ 2980	+ 1394
" (5)	+ 4141	+ 2343

The latitude is 4,141 and the departure 2,343. Dividing the one by the other we get the tangent. Then orienting the transit at 270 degrees, due west, and turning the angle, 60° 30′ we run the line, S. 29° 30 W., back across the lake. If everything is right, should strike the hub at 19 + 40 (Station 1).

Triangulating.—It will be necessary to triangulate across the lake. Though rather wide for a "sight," this may readily be done. The transit-man, on approaching the bank of the lake, drives a hub, and, having taken his back-sight, sets his instrument in the same direction forward, and signals to his flagman, on the opposite bank of the lake, who, on getting the line, drives his hub there, at B.

The transit-man must now choose a point somewhere on the edge of the lake to the west, unobstructed by trees, if possible. Such a point can usually be secured without much cutting on a lake. A flagman must be there to get a point, and, on reading the angle on this point, C, moves his transit there and sets up. Taking a back-sight with transit set at zero, the first triangulation point, A, he reads the angle to B, and then proceeds to measure the distance, C B, for a base. He has secured two angles, A and C, and the base, C B, and calculates the distance, A B, before proceeding further. The calculation of this triangle is shown on the plan, as well as the triangle, shown dotted, and the lettering of the three angles, A, B and C. Taking the log. of sin. C, 86° 10′, the cos. of A, 31° 50′,

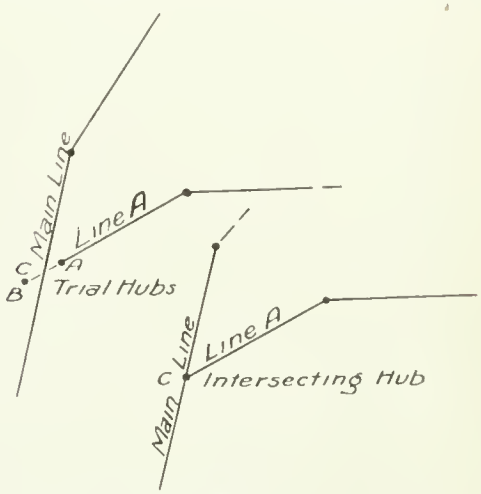

Fig. 2.—Showing Method of Intersecting.

and the log. of a′, 1,200 ft., we get the distance A B. Then taking a back-sight from B to A, the line is projected forward to the hub at Station 19 + 10.

In all these operations we have used no protractor nor angle-measure. We depend entirely on our sines and cosines, or latitudes and departures. It may be mentioned that this method is used in all important new lines of railway. Engineers prefer plotting by deflecture angles, as it involves no mathematics, and it is quick and simple, but open to many errors.

Intersecting.—In running a railway line it is usually necessary to run several lines through some portions of the country in order to get a line that is satisfactory to the surveyor. These several lines are tied to the main or first line in almost every case. We come to a lake, perhaps, and are undecided (if the lake is a large one) which bank of the lake to run or line along. If the country is wooded, as a good deal of country is in Canada still, the better side will not be known until we run a line on both. When the farther end of the lake is reached we tie one line to the other. In many cases we shall have to intersect, particularly if we are running through thick woods. In a clear, level country we can easily see the hub of the main line, and bear on it. Intersecting is rather bothersome, but the refinement of every action required to make a true intersection has its merits.

Fig. 2 shows a line, A, intersecting on the main line, the first operation and the completion. On reaching the line already run, i.e., the "main line," the flagman, after

ranging the line, just arrived at, sets for a point about a foot *from* the line, at A. Here, at A, he drives a temporary hub and drives a nail in the point. Immediately on the far side of the line, and also about a foot from it, he drives another temporary hub, B. The transit-man now comes along and sets up on the nearest hub of the main line or line to be crossed or tied to, as need be. Getting a back-sight, he looks ahead to get a hub exactly in line, and also precisely in line with the two temporary hubs, A and B. The picketman approximates the position of this hub and drives it, at C. With a straightedge or piece of the chain stretched across the nail-points of the two temporary hubs, he marks a line on the centre hub, C, in range, of course, with line A. Now, the picket signals the transit-man for a point on this pencil-line on the centre or permanent hub, C, and when he gets that point he drives the nail. This nail in hub C is then precisely in line with the position of line A, and also in line with the position of the main line. It is exactly at the intersection of the two lines. If the transit is now set up

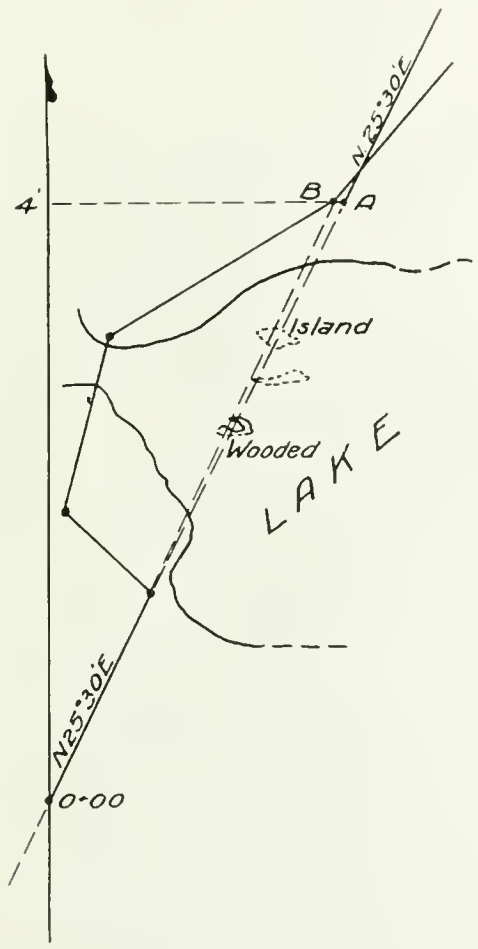

Fig. 3.

on the intersecting hub, C (the hubs A and B being pulled up) and the bearing of the line "A" taken, then orienting the transit on the main line, and noting the deflection angle, he gets the bearing of the line he has just struck —the main line in this case. If he ran that line himself, he will know its bearing and can make comparison. The lines may not close in bearings—may possibly be ten, twenty or forty minutes out, and will not connect or tie on the plot, but that is another story.

When One Cannot Sight Across the Lake.—Frequently it is impossible to sight across the lake on account of its being too wide, or on account of islands covered with bush intervening. This is a peculiar case, but in some surveys may arise frequently. For example, there were islands in this lake, already referred to, on the line of sight of our first bearing, N. 25° 30′ E., and we could not sight across, as shown in Fig. 3. In such cases we proceed in the same way around the lake by a traverse to B (Fig. 3), which is the same point as Station 4′ (62 + 40), (Fig. 1). On reaching the point B (Fig. 3), that is, Station 62 + 40, which has a bearing of N. 60° 25′ E., we judge we are approximately near the line, if produced from the first bearing across the lake. We then get our latitude and departures to determine our exact position.

By looking over the table, we find in column 9 that this point has a latitude of 4,704, and a departure of 2,216, which gives a tangent of 25° 12′. In other words, the bearing of B (Fig. 3), or Station 62 + 40 (Fig. 1), from 0 + 00 (starting point) is N. 25° 12′ E.; that is, B (Fig. 3) bears N. 25° 12′ E. from 0 + 00. But the bearing we want is N. 25° 30′ E. Looking up our table of latitudes, the latitude of B is 4,704. This sum multiplied by the natural tangent of 25° 30′, which is 4,770, gives the desired departure, viz., 2,243, which is the departure of point, A. We have already ascertained the departure of point B, and the difference between A and B is 27 ft. In order to get on the line we must increase our departure 27 ft. We now set the transit up at B (Fig. 3), or Station 62 + 40 (Fig. 1), and measure exactly 27 ft. due east, when we are in the direct line of our first bearing. A hub is driven here, of course. We now set up at A, take our bearing, N. 25° 30 E., when we proceed in a direct line, at A (Fig. 1). From the starting point, 0 + 00, to A, is easily calculated, being, as we know, the latitude and departure, and the angle 25° 30′.

Lat. 4,704 ÷ nat. cos. 25° 30 = radius, equals distance from starting point, 0 + 00 to A = 5,214. It is by this method, or a modification of it, we locate the line on the projected preliminary plan. No up-to-date surveyor projects a railway location by deflection angles with the aid of a protractor. On first-class roads the protractor is barred. All bearings of both preliminary and location are projected upon the map or plan by the method of co-ordinates, latitudes and departures; sines, cosines and tangents.

Canal statistics for the season, which is now practically closed, exceed all previous records. Up to the present time 46,428,283 tons of freight have passed through the canals, an increase of 4,845,171 tons. Of this, the Soo canal is credited with an increase of 3,384,713 tons, the Welland 729,-713 tons, and the St. Lawrence canals 851,569 tons.

It is announced that the first Canadian Roads Congress, a national convention arising out of the needs of all the provinces for better highway facilities, is planned to be held in Montreal during the coming winter. The federal and provincial governments are co-operating with the Automobile Club of Canada, as well as the local and foreign road associations, boards of trade, municipal and county councils and societies in general, to make the congress of great value to the good roads movement.

Another Alaskan railroad to open the natural resources of the territory is proposed in a bill Chairman Houston, of the Territories Committee, has favorably reported to the House. The road, to be built by the Government and either leased or Government operated, would run from the southern coast at Cordova or Seward or their vicinity to the upper Yukon River, and would not be more than 722 miles long.

CANADA'S PROJECTS OF WATERWAY IMPROVEMENT.

The Hon. J. D. Hazen, Minister of Marine and Fisheries, addressed the tenth annual convention of the National Rivers and Harbor Congress, held recently at Washington, D.C., on the great projects of waterway improvement under contract or in contemplation in the Dominion of Canada.

It was pointed out by Mr. Hazen that Montreal, the chief port of Canada, affords the best example of modern harbor works and equipment and has special advantages over any port on the North American continent from its inland situation in regard to discharging of cargo and affording communication by water via the Great Lakes to a point 1900 miles farther inland at the head of Lake Superior. Mr. Hazen referred briefly to the great growth in trade at Montreal which has made necessary the deepening of the channel in the St. Lawrence River at a cost up to the present of $16,000,000; and which will be greatly augmented by the work now in progress.

Mr. Hazen pointed out also improvements under way or to be undertaken at other ports: at Quebec harbor, the lock and dam on the St. Charles River to cost $3,000,000; at St. John, improvements to cost millions, one contract alone amounting to $7,500,000; at Halifax, the reconstruction of deep-water terminals to cost over $8,200,000; the new breakwater 5,500 feet in length under construction at the twin ports of Fort William and Port Arthur; the many new drydocks, etc., at numerous smaller intervening ports, and at Vancouver and Victoria the government wharf and breakwater respectively, totalling a general cost of $5,500,000.

In connection with Canada's canal question, Mr. Hazen said: "Canada and the United States jointly operate one of the largest systems of Inland waterways in the world, a most valuable heritage for purposes of transportation. This whole system of canals on both sides of the line is free of tolls, and open to the vessels of both countries. The Canadian canal system represents a capital cost of $104,000,000. If to this, however, is added the capital cost of harbors, the dredging of channels, lighthouses, buoys, etc., it will be found that Canada has contributed upwards of $365,000,000 all told for the establishment of means of transportation by water."

He mentioned that the whole scheme for the Trent Canal is now being carried out; that the new Welland Canal is already under construction, and is to aggregate a cost in the neighborhood of fifty million dollars; and that the construction of the Georgian Bay Canal is one of the schemes contemplated for the near future.

Mr. Hazen closed his address by remarking that the Canadian Government has entered actively upon "the project of affording facilities at all our great national ports which will enable them to compete on at least even terms with any other ports on this continent."

German capitalists headed by Capt. Von Der Osten, of Berlin, have secured from the provincial government a concession of forty square miles near Sussex, N.B., and will prospect for salt, gypsum ore, potassium and petroleum. The project is capitalized at three million dollars, and in particular the promoters expect to develop a big industry in potassium, which is known to exist in large quantities, and for which the United States offers an almost unlimited market.

THE CORROSION OF WATER MAINS.*

By William Ransom, A.M.I.C.E.

THE subject of the corrosion of iron mains is one of great importance to waterworks engineers, who naturally desire to obtain as long a life as possible for their water mains, and also are anxious to use such materials as will not impart any impurity or deleterious property to the water in the course of its distribution. The need for investigation and conference on the subject can be realized and its practical importance better understood when the recent case of a town in South Africa is mentioned, where a new steel water main has become so pitted with rust that it has become necessary to partly replace it with a cast-iron main. It was found that the damage was due to the sulphuric acid in the soil resulting from the oxidation of pyrites in the soil. Other portions of the main have been protected by covering with two thicknesses of bituminized Hessian cloth, and afterwards coated with a bituminous composition.

The writer had his special attention drawn to this subject in connection with some investigations he made with regard to a town water supply which not only corroded the mains but deposited a brown percipitant upon exposure, and caused an objectionable discoloration to domestic utensils, etc., while at times an unpleasant smell was noticed when the water was drawn from the mains.

We are all familiar with the ordinary formation of rust, but there are many factors at work to complicate the corrosion of water mains, and in this short paper the writer can only hope to refer to one or two phases of the subject in which he has been especially interested.

Dry oxygen has no effect upon iron at normal temperature, but if the iron be heated oxidation takes place and a black scale or oxide forms on the surface, which, when the metal is heated to white heat, is represented by the formula Fe_3O_4. This is the scale which, being non-adherent, is brushed off the hot plates after they have passed through the rolling mills.

It is when moisture is present together with carbonic dioxide that oxygen is able to act most readily upon iron at the ordinary temperature and a brown hydrate of ferric oxide if formed. Water, which contains free CO_2, and is therefore a weak acid solution, will very quickly corrode the iron mains through which it is being distributed. The rust that is formed is not a protective coat, for it is hygroscopic, and fresh water is brought into contact with the iron to continue the process of oxidation. The chemical action produces a certain amount of heat, which also helps in the work of oxidation. The various impurities in the water and the different qualities of iron modify or complicate the corrosive effect on the mains and the discoloration caused to the water. The ordinary action of corrosion is prevented by giving the iron a protective coat of some bitumastic material, but there is great difficulty in ensuring perfect protection, for pinholes, etc., may soon form centres for the formation of rust.

There have been many investigators who have made a special study of the formation of rust. Wehner, of Munich, in 1907 summarized the various forms of rust under three headings: Firstly, coarse blotches or blisters of rust which are formed on the interior of water mains and on the exterior of pipes laid in damp or salt soil. Pro-

*A paper read at the meeting of the Institution of Civil Engineers, held at Birmingham on Nov. 20, 1913.

fessor James Campbell Brown likens this rust to the limpets which are found on a rocky sea coast, and found that they grow by addition of concentric layers. This incrustation will keep on extending, and in large mains may form a layer 1 in. to 1½ in. in thickness. If this be removed or the surface disturbed the incrustation will go on reforming. Secondly, a fine and more or less brightly tinted mud of a yellowish tinge, which is found deposited in the interior of pipes. Thirdly, graphitic destruction of iron, which is effected by weak acids, and causes the iron to assume a spongy nature. There is no outward indication of rust, and Wehner has found that this form of rust can take place, leaving a protective coating apparently undamaged. This fact emphasizes the necessity of care in selecting suitable materials for the manufacture of water mains.

The production of rust, especially in water service pipes, is often much accelerated by electric action. If there be two metals an electric disturbance is produced, and if the metals be conductors one will become electro-positive and the other electro-negative. If the water be slightly acid current is able to circulate, and the chemical action previously referred to at once comes into operation, and the electro-positive metal is attacked. Galvanized pipes are preserved from ordinary corrosion, but if the protective coating of zinc be cracked or has been imperfectly applied, electro-action will be set up, destroying the zinc, and exposing the iron to the ordinary action of the water. Hydrogen will at the same time be liberated, and impart an unpleasant smell to the water.

Waters which become discolored during the process of distribution and choke the mains with a brown deposit are chiefly those in which the presence of free CO_2 is able to intensify the ordinary action of rusting.

The chemical action can be briefly explained as follows: The water containig the free CO_2 forms a weak acid solution, and, attacking the iron pipes, produces ferrous carbonate or bi-carbonate, liberating hydrogen in the process, thus:

$$H_2O + CO_2 + Fe = FeCO_2 + 2H.$$

If the ferrous carbonate absorbs oxygen from the water or the air it oxidizes, and a brown hydrate is produced, while CO_2 is liberated which is ready to attack fresh iron. It will, therefore, be seen what an important bearing even a very small proportion of free CO_2 present in the water has upon the life of the main and the color of the water.

Ferrous carbonate is insoluble in water, and would quickly completely choke the mains but for the fact that it is dissolved in water which contains CO_2, while by the absorption of more CO_2 it becomes a bi-carbonate which is soluble in water, and is passed on to the consumer to be drawn off at the tap. If this bi-carbonate has not been able to absorb oxygen whilst in the mains the water when drawn from the tap will be clear and free from turbidity until, by combining with oxygen from the air after the water has been standing sufficiently long, the water will gradually become turbid, and then precipitate the brown hydrate. If the bi-carbonate has been able to absorb oxygen in the mains the water is drawn off in a turbid condition, and will gradually become clear, leaving the brown hydrate precipitate. If the water has been pumped and air sucked in, the above action is very much intensified, and if the water be allowed to remain stagnant in the mains serious deposit will occur. The mains would quickly become choked unless they are frequently flushed, while the water will be very much discolored.

We have seen how that hydrogen is liberated in the process of chemical action, and imparts an unpleasant smell to the water. This is naturally increased if the water remains stagnant in the mains to allow time for the hydrogen to accumulate, and the remedy is to liberate the hydrogen by frequent flushing of the mains and the avoidance of dead ends.

Where a public water supply is of such a nature as to produce the results above described, the problem is how to prevent the action of the free carbonic acid upon the mains, so as to fit the water for domestic and laundry use. We see in nature where water containing CO_2 has dissolved iron from the minerals with which it has come in contact during its passage through the soil, how upon exposure the ferrous bi-carbonate is deposited in the brown form so familiar to us in the watercourses and streams of iron districts. Household utensils and domestic sanitary appliances are soon stained by the use of such waters, while it is quite impossible to use the same for laundry purposes. Cisterns and pipes will become choked with the brown deposit, and from the consumer's point of view the question becomes of very great importance, especially as it is found to be more difficult to deal with waters which have such action than with those which bring iron with them in solution from their source.

The removal of the free CO_2 appears to be the only certain way of preventing the action of such waters upon the iron mains, and the passing on of ferrous bi-carbonate to the consumer, which, by absorption of oxygen, causes turbidity and the brown deposit.

Oeston, of Munich, mentions a peculiar case, where, in 1908, at Berlin, a water had been treated for the removal of iron. The carbonic acid gas, however, had not been eliminated, and upon examination of the water drawn from the cast-iron mains of the Berlin Zoological Gardens it was found, owing to the corrosion of the mains by the Co_2, that the percentage of iron had again risen, and the work of removing the iron from the water at its source was wasted. He also found that the greater the pressure in the mains the greater was the action of the carbonic acid gas upon iron.

In connection with the ground water supply of Frankfurt-am-Main, where the free Co_2 existed to the extent of 3 parts per 10,000, Scheelhaase describes an apparatus for the removal of the Co_2. The water passes through a special marble aerator, and is allowed to fall in the form of spray over the marble, which absorbs a large proportion of the CO_2, but the hardness of the water is increased by the formation of a bi-carbonate. The destructive action of the water upon the mains has ceased, and the cost of the process is given at about one-tenth of a penny per 1,000 gallons treated.

The writer does not propose to deal in this paper with the deposits of calcium carbonate caused by hard water, and the well-known processes of softening such waters; but it is well to bear in mind that such hard waters give a protective coat to the mains against the ordinary action of corrosion.

Dr. Hartwig Klut, of Munich, made a special study in 1907 of carbonic acid gas in relation to water supplies, and he found that when oxygen is present with CO_2 the latter acts upon the lead service pipes, and there is the danger of lead poisoning.

The Massachusetts Board of Health have made experiments with similar results. The removal of free CO_2 is therefore necessary in some cases to prevent the danger

of lead poisoning where the water passes through lead service pipes.

At Dessau, in Anhalt, where the water is very soft and contains so much CO_2 that lead was dissolved from the service pipes, the excess CO_2 has been removed by the addition of powdered carbonate of lime.

Many waters are contaminated with iron at the source of supply, and this iron not only imparts an unpleasant taste, but is a cause of deposit in the mains rather than a cause of corrosion. Such waters, if rendered slightly acid by vegetable matters, such as peat, deposit a ferruginous slime in the mains, caused by the growth of an organism known as Crenothrix, which is able to thrive under such favoring conditions. The dead organisms impart a bad taste to the water. The remedy is to remove the organic feeding matter by filtration and the iron by aeration. If the acid be neutralized, the iron organisms are not able to develop.

In North Germany, at Konigsberg, 90 per cent. of the iron in solution is removed by aeration. The water is delivered in a fine spray over coke filters, and ferric oxide is deposited in the coke.

The organism causing the black slime has been specially examined by Migula, of Carlsruhe, and has been given the name of Chlamydothrix. He says that the germs come with the water, and attach themselves to the inner surface of the mains. From minute specks of jelly the organisms develop into threads, while iron oxide is deposited by the organisms in the process of growth.

Professor James Campbell Brown says that waters which deposit black slime invariably contain an appreciable quantity of iron in solution in combination with organic matter of an acid character. He thinks that the slime organisms live on the carbon compounds which are found in a soluble organic compound of iron, and iron oxide is deposited throughout their growth.

The flocculent matter which is thus deposited by such iron organisms must not be confused with the corrosion of the mains caused by chemical action and subsequent deposit of the iron dissolved from the mains.

COST OF CONCRETE ROAD.

IN the following itemized table the compiler, Mr. B. P. Lampert, county engineer, Emery, Ia., gives the cost of building a concrete road at Fort Dodge, Ia. Points to be taken into consideration when studying the data are: (1) Average haul, 2½ miles; (2) sand not screened and not charged; (3) engineer's time included, also 1/5 cost of plant used.

Total amount laid, 9,472 square yards. Approximately 3,100 cubic yards of grading (cut and fill).

Labor on Concrete.

Based on average organization and average rate of 500 square yards daily.

No. of men.	Job.	Cost per day.	Cost per sq. yd.
2	Finishing and removing forms	$ 8.00	$0.0160
2	Striking off concrete	5.50	0.0110
1	Fireman on mixer	3.50	0.0070
1	Engineer on mixer	4.00	0.0080
2	Side forms and joints	6.00	0.0120
1	Cement	3.00	0.0060
2	Wheeling and shoveling sand	5.50	0.0110
3	Wheeling stone	8.25	0.0165
6	Shoveling stone	10.50	0.0330
1	Extra, fixing subgrade	2.75	0.0055
1	Water boy	1.00	0.0020
1	Hose boy	1.00	0.0020
23		$65.00	$0.1300

*Not included in calculating cost.

A steel dipper dredge of 5 yards' capacity is being completed by the M. Beatty and Sons, Limited, Welland, for the C. S. Boone Dredging and Construction Company, of Toronto, for use in harbor improvement work. The dredge has a hull of 100 feet in length with 40-foot beam, and 10 feet in depth. It is similar to those now being used by the Canadian Dredging Company, Midland; the Dominion Dredging Company, Quebec, and others. It has been used on a wide variety of work, and has established good records for capacity, and low cost of maintenance.

SEMI-STEEL CASTINGS.

In a paper read recently, by Mr. R. H. Probert, to the Ohio Society of Engineers it was stated that one of the principal points in making semi-steel is to have the metal hot. To get the best results and to insure a thorough mixing of the iron and steel when tapping, the metal is run into the tapping ladle, which is tilted enough to run the metal into a shank or bull ladle. The latter also is tilted to allow pouring the metal into the hand or crane ladles. When melting for castings weighing from 2,000 to 8,000 lbs. each, the crane ladle is of sufficient capacity to hold the entire amount of metal required, and into this ladle is placed 5 lbs. of 80 per cent. ferro-manganese to each ton of iron. This method of tapping permits the steel and iron to mix thoroughly in the ladles before pouring the metal into the molds.

In mixing metal for high-grade castings that are required to stand up under high pressure and high speeds, the pig iron is charged on the bed and the steel scrap on top of this charge of pig iron. Charges amounting to 2,500 lbs. each in a 40-in. cupola are as follows:

Coke	1,000 lbs.
Pig iron	1,000 "
Gray iron scrap	500 "
Steel scrap	500 "
Pig iron	500 "
Coke	250 "

The coke bed must be large enough so that the first iron will come hot. Having tapped the metal white hot, it must be poured into the molds as nearly as possible at that heat. The hotter the iron the greater should be the care taken in venting the molds, as the more resistance and refractory the mold, the more care and skill is required in feeding the hot metal into the mold.

The steel used is boiler-plate scrap from ¼ to 7/16 in. thick, either square or rectangular pieces, from 6 to 18 in. long. The steel scrap is not charged directly on top of the coke bed, but, as previously stated, about 150 lbs. of coke are charged on top of steel scrap before charging the next layer of pig iron.

Careful attention is given to the charging of the cupola throughout the various heats including the firing of the coke bed before the first charge of pig iron is placed in the cupola. By doing so, dull metal is avoided during the whole of the heats for the day's melt.

The range of analysis of the boiler-plate scrap, which consists of shell, firebox and flange steel, is as follows:

	Per cent.	
Sulphur	0.022	0.038
Phosphorus	0.015	0.020
Carbon	0.12	0.18
Manganese	0.34	0.45

In 25 minutes after the blast is turned on the metal is ready to be tapped and drawn off.

Recently several semi-steel flywheels about 9 ft. 6 in. in diameter, each weighing 7,500 lbs., were successfully cast without difficulty or loss. They were for special service, to run at a peripheral speed of 12,000 ft. per min. The castings proved to be clean, solid, without flaws, the metal was tough, but not hard, and the turnings curled from the tool like pine shavings. The steel scrap amounted to 25 per cent. of the charge. The transverse tests on a ¾-in. square bar with 12-in. supports averaged 1,625 lbs.

The analysis averaged:

	Per cent.
Silicon	1.41
Manganese	0.36
Phosphorus	0.462
Sulphur	0.122
Combined carbon	0.95
Graphitic carbon	2.46

The analysis of the pig iron charged with the gray iron and steel scrap averaged:

	Per cent.
Silicon	1.65 to 2.75
Sulphur	0.035 to 0.054
Phosphorus	0.322 to 0.754
Manganese	0.55 to 0.85

Small and medium-sized castings that are cored and of peculiar shape, weighing from 400 to 500 lbs. each, that are required to stand up under constant high duty, are made as previously stated, showing the same analysis in the pig iron and in the finished castings.

Gas-engine cylinders each weighing about 1,650 lbs. for 50-h.p. engines, were successfully made from semi-steel. The metals charged were No. 2 foundry pig iron, gray iron scrap and the steel scrap amounted to 30 per cent. of the charge. The transverse tests on ¾-in. square bars, with points of support 12 in. apart, averaged 1,755 lbs. The deflection amounted to 0.22 in. The cylinders were solid, clean and tough. They were easily machined and the bore showed excellent, smooth finish. The fractures on the test bars were fine and close grained and took a very fine finish when machined, draw-filed and polished.

The cylinders were poured on end, the molds were skin-dried and were provided with ample pouring basins, down gates or leaders and large risers. The shrinkage was about 3/32 in. to the foot, but on castings poured in a horizontal position the shrinkage is about 7/64 in. per foot.

In making the molds the best results are obtained by working the sand as dry as possible, not sponging the patterns around their ends and sides, as the water will dampen the edges of the molds and will result in making the castings hard on their outside edges—too hard to machine profitably.

Provide the molds with a pouring basin and well, and do not depend on one large down gate or leader. When making medium and small work, use a strainer gate, which is a pouring basin on the top surface of the cope, with sufficient down runners of small diameter to a gate below in the surface of the drag. These runners will prevent the lighter metal and other impurities from running down into the body of the mold, resulting in clean, solid castings. Large molds should be skin-dried, and all molds for semi-steel castings provided with ample pouring basins, down runners, gates, risers, etc.

The flasks should be strongly made, as the mold strain is entirely within itself and on heavy castings the flasks must be well braced and banded around cope and drag to counteract the great strains on the mold.

Semi-steel can be used in such castings as cylinders, pistons and plungers for steam, gas, ammonia and hydraulic work, engine and machine beds, flange couplings, bearing boxes, large flanges, brackets, pedestals, pinions and gear segments, forming dies for sheet metal, electric motor castings, etc.

It takes no more coke or labor to melt semi-steel than it does to melt gray iron—1 lb. coke to 7 and 7½ lbs. of iron.

THE POLLUTION OF INTERNATIONAL WATERWAYS.

When the International Joint Commission meets next month it is quite likely that it will draft recommendations to the Canadian and United States Governments that will accentuate considerably the attitude of both countries with respect to the water pollution along about 2,000 miles of boundary line. Both countries have numerous cities that are deeply concerned in the investigation, and whether or not this winter will see legislation enacted to curtail the use of lakes and especially of rivers as general receptacles for all manner of refuse and waste, the report, in itself, will fill a most important mission, by revealing the present dangers that beset these riparian communities. The report will cover five waterways, viz., Niagara River; Detroit River and connecting waterways from Lake Huron to Lake Erie; St. Mary's River; St. Lawrence River from Lake Ontario to a point where it departs from the boundary; and a portion of the St. John River.

The Niagara River situation is the most acute. All the sewage from Buffalo, Tonawanda, North Tonawanda and Niagara Falls, N.Y., is discharged in raw state directly into the river, and the sewage of Lackawanna is discharged untreated into Smoke's Creek, whose outlet is 1½ miles above the head of the river. The population of the territory thus draining directly into the Niagara River from the New York State side, and above the Falls, is estimated at 615,000. All of these cities, together with numerous villages near the river bank, and the city of Lockport, with a population of about 20,000, take their water supplies directly from the river.

The Detroit River, and its connecting waterways, furnish a problem possibly greater than the Niagara conditions. The other points of investigation are likewise important to the people of both countries.

The International Joint Commission was assigned its task on August 1st, 1912, by the two Governments. The questions referred to it are as follows:—

1. To what extent and by what causes and in what localities have the boundary waters between the United States and Canada been polluted so as to be injurious to the public health and unfit for domestic or other uses?

2. In what way or manner, whether by the construction and operation of suitable drainage canals or plants at convenient points or otherwise, is it possible and advisable to remedy or prevent the pollution of these waters, and by what means or arrangement can the proper construction or operation of remedial or preventive works, or a system or method of rendering these waters sanitary and suitable for domestic and other uses, be best secured and maintained in order to insure the adequate protection and development of all interests involved on both sides of the boundary, and to fulfil the obligations undertaken in Article IV. of the waterways treaty of January 11, 1909, between the United States and Great Britain, in which it is agreed that the waters therein defined as boundary waters and waters flowing across the boundary shall not be polluted on either side to the injury of health or property on the other?

The questions were considered at the October 1912, meeting of the Commission at Ottawa, and upon later advice as to the scope of the investigation, various meetings were held during the winter for the working out of all details. It was decided that the investigation should include a bacteriological examination of samples

of water taken, including the bacteria count and the qualitative and quantitative estimation of B. Coli, according to standard methods, and such chemical examination as might be deemed necessary. Dr. Allan J. McLaughlin, of the U.S. Public Health Service; Dr. J. W. S. McCullough, chief health officer of Ontario, and Dr. John Amyot, professor of hygiene, University of Toronto, have been actively engaged in these bacteriological examinations during the past summer and have very recently submitted their report.

Mr. Frank S. Streeter, representing the United States, and Mr. Henry A. Powell, representing Canada, constituted a committee which, pending the above report, looked after the gathering of such testimony from parties interested as might seem desirable in forwarding the investigation.

The Commission's findings will, as stated, be published shortly. It is generally understood that while they are not alarming they will disclose conditions that will necessarily be remedied to conform to the health conditions stipulated in Article IV., above referred to, of the waterways treaty.

THE CORROSION OF WATER MAINS.

The subject of pipe corrosion is one which necessarily interests engineers and manufacturers in their efforts to obtain durability and long life in water mains. The paper by Mr. Hale, read before the American Public Health Association, and published in December 4th issue of *The Canadian Engineer*, and the article by Mr. William Ransom appearing in this issue, contain a great deal of valuable information concerning corrosion from various causes.

There is no difficulty in realizing the need for sound investigation and conference on the subject, as every waterworks engineer is naturally desirous to use materials that will be durable, and that will not impart any impurity to the water, nor furnish it with any deleterious property in its course of distribution.

Mr. Ransom refers to a particular instance where a new water main had been laid down and which, after a brief duration of service, became so pitted with rust that it was found necessary to remove a portion of the distributing system and replace it, the damage being caused by the presence of free sulphuric acid in the soil, due to the oxidation of iron pyrites. He also calls attention to the fact that corrosion by electrolytic action is often much more serious than is commonly thought to be the case.

Mr. Hale refers to numerous sources of corrosion to be found in both raw and treated waters, the action being more pronounced when the metal is clean and free from incrustation, which forms a protective coating, depending upon the nature of the water, delaying the corrosion and reducing the resulting percentage of iron in the distribution service.

A third writer on the subject, Mr. E. K. Rideal, in a paper to the Society of Engineers (England) strongly supports the electrolytic theory of corrosion. He expresses his belief that the theory is perfectly tenable when due attention is paid to considerations such as alterations in the solution pressures on crystal surfaces, and the phenomenon of passivity shown by iron.

According to Mr. Rideal, corrosion is due either to internally generated electric currents or to those from external sources. The theory is applicable to the problems of rusting in reinforced concrete, water-pipes and structural iron-work, as well as to the action of stray currents from street railway circuits, damp electric-light leads and telephone cables. In the light of that theory both the plating of iron with metals, or covering the surfaces with paints and varnishes, are to be regarded as means to an end, namely, to prevent the formation of local "corrosion cells." The effect of pitting in steel pipes is to be attributed to inclusions of slag and oxides of iron. Metallic coatings must be perfectly uniform in character, otherwise rusting may be augmented instead of retarded by such processes, while paints should be applied to clean surfaces and should possess certain definite characteristics, such as high specific electrical resistance, a pigmentary vehicle that does not readily liberate water during the process of aerial autoxidation and is not permeable to water vapor when thus oxidized, and pigmentary particles not widely separated from iron in their electrochemical potential.

LETTERS TO THE EDITOR.

Re "Stresses in Circular Pipes."

Sir,—With reference to Mr. Hogg's article on "Stresses in Circular Pipes," which appeared in your issue of November 13th, while I cannot offer any detailed discussion upon it, one or two points may be noted. Mr. Hogg has applied the ordinary formulæ for the arch rib to determine the bending moments in a thin circular pipe due to the hydrostatic pressures exerted by the water, which it contains when just full, and supported on a horizontal knife edge below the pipe. The effect of putting the water under pressure, as in the case of a conduit conveying water to a turbine seems to have been considered only as producing a circumferential tension in the ring. The influence of this tension in determining the changes in the vertical and horizontal diameters of the ring does not appear to be touched upon, and while Mr. Hogg may have satisfied himself that an effect of this nature is insignificant as compared with the deformations which he has calculated, it does not appear in the analysis. If the pressure is very great in the pipe, then the deformations due to the weight of water in the pipe are, as Mr. Hogg says, insignificant; while if the pipe merely contains water which is not under pressure, those deformations are the only ones to be considered. Not having investigated such effects numerically, as Mr. Hogg has probably done, I cannot venture a suggestion as to their relative importance in determining Δx and Δy, and it would be interesting to have the deformations worked out for a pipe, say 6 or 8 ft. in diameter, under different heads of up to, say, 200 feet. If Mr. Hogg has such data perhaps he will publish it.

There are some misprints to be noted. On page 696 in the first equation for MD the integral should not contain the term (1–Cos ϕ). The subsequent expression found by substitution for Sin $\phi\ dp$ is, however, correct. On page 689, the expression for dp in the right hand column evaluates to $\frac{-r\,(\frac{1}{2}+k)}{H+(1+k)\frac{r}{r}}$, and not as stated. On page 697 in Fig. 3 there are too many x's and the text is not readily connected with the figure. I have not checked the analysis in detail, but as it follows along conventional lines

there is little likelihood of error arising. The chief interest of the investigation, to my opinion, would be in the presentation of comparative figures along the lines which I have suggested, but I do not think there is a great field for discussion.

Engineers are well aware of the existence of pressures due to earth loads, of the differences between a supporting saddle and a theoretical knife edge below the pipe, and of the necessity of modifying theoretical deductions based on assumptions which are necessarily so much at variance with the actual conditions. But such modifications are matters of judgment or even arbitrary opinion, rather than the result of any clear line of reasoning. For such reasons I regard the earlier part of Mr. Hogg's article as possessing interest which would be increased considerably if some actual examples were given to illustrate the points which I have noted.

E. BROWN,
Professor of Applied Mechanics and Hydraulics.
McGill University, Montreal, December 1st, 1913.

Sir,—While the discussion of "Stresses in Circular Pipes" by Mr. T. H. Hogg, in your issue of November 13th, forms a valuable contribution to the literature of the subject, there are still many important problems connected with this and allied fields to which the attention of skilled investigators might be directed with profit.

In the case of the particular type of structure considered by Mr. Hogg, namely, the large conduit subjected to low internal water pressure, it would be of interest to know at what head the consideration of bending moment in the shell becomes necessary for pipes of various diameters. Some valuable work might also be done in investigating the effect of the relatively shallow earth fill existing along such pipe lines on the total stresses in the pipe. The large variation between the lateral pressure at the crown of the pipe and at its base and the uplifting effect of the earth pressure on the the lower half of the pipe place the problem outside the case considered by Professor Talbot and quoted by Mr. Hogg—that of a uniformly distributed lateral pressure acting on the vertical diameter of the pipe. In this connection it is interesting to note that since each half of the pipe lying on one side of the vertical diameter is in effect an arch, the imposition of a load of the character of the earth pressure would require, for coincidence of the curve of the shell with the line of pressures, a pipe cross-section of flattened oblate form similar to that found desirable for the resistance of low internal water pressure. Another consideration of importance to the constructor of such pipes is the proper width of the saddle or bed of concrete upon which the conduit is to rest. In the recent discussion of the "Theory of Loads on Pipes in Ditches," by A Marston and A. O. Anderson, (Bulletin No. 31, Engineering Experiment Station, Iowa State College of Agriculture and Mechanic Arts, Ames, Iowa), it has been shown that a pipe resting upon a shaped earth bed derives practically its entire support from the lowest 90 degrees of the surface. Whether a concrete bed of the same relative width would be suited to large pipes subjected to internal pressure might well be given some thought, and having arrived at the most desirable width of bed, equations for maximum moments corresponding to this condition would be found of especial value to the designer.

A promising field of enquiry related very closely to the one in which Mr. Hogg has done useful work, is that of the design of pipe culverts subjected to the pressure of earth embankments. Research pertaining to this problem does not concern the calculation of the stresses in the shell so much as the fixing of the loads applied to it. At the present time great divergence of opinion exists as to the amount of earth filling which a culvert should be figured to carry. Some engineers assume that the entire weight of earth above the structure is supported by it while others consider less than half that amount as sufficient. The effect upon the culvert of live-loads moving along the embankment is a source of probably greater disagreement. Assuredly valuable work might be done in reducing these uncertainties of loading, for, by so doing it would be possible to design culverts by a little more rational process than mere guesswork.

It is to be hoped that Mr. Hogg and other investigators of the problems relating to stresses in pipes, sewers, tubes, culverts and tunnel linings will carry their researches still further. Certainly there is no more promising field for practical mathematical research.

C. R. YOUNG.
University of Toronto, December 18th, 1913.

Sir,—Professor Brown, in his discussion of the article on "Stresses in Circular Pipes," states that the effect of putting the water under pressure seems to have been considered in the analysis, only as producing a circumferential tension in the ring, and that the influence of this tension in determining the changes in the vertical and horizontal diameters of the ring does not appear to be dealt with. The writer must apologize for having given in the discussion only the analysis of the particular case when the conduit is filled with water to the crown. The general case for water to any head above the top of the pipe has been analyzed, but the integrations are much more laborious and long drawn out. The results are exactly the same, however, as the results obtained for the particular case and given in the paper, with the exception of the amount of the tension, which of course varies with the head; the additional amount being represented by Hyr, I infer from Professor Brown's letter that he believes the deformations may be affected by the water pressures when the head is above the crown of the pipe. This is not the case, as noted on page 698 of the article, and as proved by the analysis of the general case.

It is true that, as the head increases the tension in the shell will increase, and this in turn will cause an increase in the length of the circumference. Within the elastic limit, however, this movement will be comparatively small. In any case, the values given in the article for the deformations are for the deformations due to the eccentric loading. If a person were interested in obtaining the exact amount of the shortening and lengthening of the diameter, the increase due to the stretching of the shell would have to be added or subtracted from these deformations. These figures, however, are of no practical use, since within the limits of allowable stress of the material, the stretching of the shell is exceedingly small. They might perhaps be of service in the use of concrete or concrete lined steel pipes in determining whether a coating of plaster would crack.

The writer desires to point out that the conditions of loading in a horizontal circular pipe under water pressure is very similar to the case of an eccentrically loaded column. In the case of a column, it is the eccentric load

which causes deformation in the sense of a departure from the vertical axis. The axial load on a column has no effect on the deformation in this sense, but simply shortens the column by compressing the material.

The writer regrets that the analysis of the general case of water pressure above the top of the pipe cannot be given here; space will not permit.

The misprints noted by Professor Brown are errors which have slipped in, in the hurry of preparation. Also Fig. 3 was traced by an assistant and the x's have been misplaced. A little thought, however, will clear this up when following the analysis.

The writer would like to draw attention to a fact which has been overlooked in a number of the other discussions presented, the formulæ derived, allow of the ready fixing of the stresses in such conduits, even although it may not seem desirable for construction reasons to use the hydrostatic chord in preference to the circular shape. As noted in the article, these stresses have previously been overlooked.

In answer to Mr. Young, in the writer's opinion the correct formulæ as obtained in the discussion should always be used in computing the stresses of this particular type of structure. There is little difficulty in the use of the equations for practical design and it will always be safer to compute the bending moment due to the water pressure, and include sufficient material to care for these additional stresses. As regards the point at which it becomes desirable to use the hydrostatic chord in place of the circular shape the cost of materials and local conditions will have a large bearing. It is unlikely, however, that there would be any economy in the use of the hydrostatic chord, for pipes less than 8 feet in diameter under a head of more than 50 feet. Under such conditions it would be more economical to use the circular shape, as the saving in material in the use of the chord would be more than counterbalanced by the constructional difficulties introduced by the irregularity of the shape.

It is quite true, as pointed out by Mr. Young, that the oblate form is desirable from the point of view of earth pressure. This is easily seen if we assume fluid pressure outside; in which case we get the hydrostatic arch as the most desirable form to resist the pressure.

T. H. HOGG.

Toronto, Dec. 20th, 1913.

Re "Flat Slabs."

Sir,—Mr. Elmont states that the matter regarding moments is a question of test loading. The writer will submit that Dr. Eddy pointed out that his (Mr. Elmont's) mathematics did not apply to the flat slab as built by Turner, because his theory assumed a uniform distribution of reinforcement; and, accordingly, the mathematics which he has merely copied from Grashof, does not apply to this particular construction. It is difficult, indeed, to discuss the subject of mechanics with one who, while familiar with Clapeyron's theorem, assumes that it is inapplicable to the flat plate.

Mr. Elmont's attention has been called to the fact that, under bending, energy is stored radially and circumferentially. Ordinary familiarity with the construction would impress anyone with the fact that circumferential deformation does not affect the vertical geometry of the slab; whereas, the radial deformations alone determine deflection. Hence, there is less deflection with the storage of energy partly in a circumferential direction, than where it is stored in a radial direction; and this effect on the total work of deformation is most marked, and effects the magnitude of the moments to be resisted.

This subject will be discussed very fully and completely in a long paper, about completed, for discussion in one of the large engineering societies; and it will be sufficient for the present, to state that this theory of work, properly developed, is the simplest solution of all the problems the writer has met in reinforced concrete construction; and it shows the absurd degree of error which those engineers have fallen into, who assume that the old reliable law of conservation of energy does not apply, and that corollaries derived therefrom do not apply to such a device as a reinforced concrete floor slab.

C. A. P. TURNER.

Minneapolis, Minn., December 2nd, 1913.

Sir,—The writer desires to reply that he neither stated that "the matter regarding moments is a question of test loading" nor that Clapeyron's theorem could not be applied to flat slabs.

As regards Grashof's theory on flat plates and slabs, which Mr. Turner now deems inapplicable to the Eddy-Turner flat slab design, the writer would say that he fails to see that their design is so defective that it is not even governed by that theory, which is simply built up from the fundamental equations of external stress and strain, as Dr. Eddy also has expressed it in his and Mr. Turner's joint opus entitled "Flat Plate Theory." It is strange that Mr. Turner has only recently discovered the usefulness of the theory of work, while other structural engineers have employed it for years as the general basis for calculation of statically indeterminate structures. By further study Mr. Turner will find that also Grashof's formulæ can be derived from it.

The conclusion the writer drew from the results arrived at in his paper on "Bending Moments in Flat Slabs" was merely that a certain type of flat slab, which includes Messrs. Eddy-Turner's, could be improved by arranging reinforcement as described in the paper.

V. J. ELMONT.

Montreal, December 9th, 1913.

At the annual meeting of the directors of the American Highway Association, the announcement was made that Atlanta had been selected by the executive committee and that the convention would be held there from October 19th, to October 26th, 1914. The selection of Atlanta was due to the fact that the committee considered the south entitled to the annual congress in 1914 as the east was recognized at the 1912 meeting, the north-west at the 1913 meeting and the far west will receive the 1915 meeting. The unique experiment by Georgia in working the entire state convict force on the roads will afford an interesting study to the delegates, while the stimulation afforded by the great good roads assemblage will probably hasten the establishment of state highway departments throughout the southern states.

The Dominion Iron and Steel Company, of Sydney, N.S., are preparing to install a new furnace in their rolling mill department with a view of developing an output of soft steel in addition to the other products at present manufactured. It was at first intended to establish a number of extra soaking-pits in the blooming mill division, but it was finally decided to adopt the furnace for the soft steel production. New tables are also shortly to be put in the rolling mill to replace those which have been in use for a long period.

CONVENTION OF THE AMERICAN ROAD BUILDERS' ASSOCIATION.

THE tenth annual meeting of the American Road Builders' Association was held in Philadelphia, December 9th to 12th inclusive. It is stated that the attendance exceeded in good measure any of the previous sessions. The registration of members and delegates approximated 1,100.

The convention was officially opened on Tuesday afternoon, December 9th, by Governor Tener, of Pennsylvania, who delivered an address on the good roads movement, in which he passed very commendatory remarks respecting the efforts of the various organizations and the receptive mood of the popular mind in the interests of road improvement.

Col. E. A. Stevens, Commissioner of the Department of Public Roads of New Jersey, read a paper on "Highway Officials, Their Duties and Powers," which dealt with the subject in considerable detail. It was followed by a discussion opened by Mr. A. N. Johnson, State Highway Engineer, Illinois, who explained fully the methods of road administration adopted by his and other States, emphasizing the dependency of success upon the "pay-as-you-go" system. Mr. A. R. Hirst, who occupies a similar position in Wisconsin, described the new road laws and the fundamentals of road making and maintenence with which he had to do. He enumerated the ways in which Wisconsin roads were financed to be as follows:

(1) A municipality, the county and the State may bear equal shares of the expense.

(2) The county may assume two-thirds.

(3) A private citizen may guarantee one-sixth of the total expenditure.

"Division of Expanse, Responsibility and Authority Between Nation, State, County and Town" constituted a paper read by Mr. S. P. Hooker, Superintendent of Highways of New Hampshire, in which were explained the various methods that have been proposed for federal aid toward road construction. In this connection, he emphasized the fact that the question of federal aid should be given very careful consideration, and that any accepted arrangement for the extension of same, should be most wisely handled.

Mr. Nelson P. Lewis, Chief Engineer of the Board of Estimate and Apportionment of New York City, opened the discussion and emphasized Mr. Hooker's cautionary remarks concerning the neglect of careful consideration and planning as evidenced by previous cases where federal aid has been extended. Mr. Harold Parker, ex-chairman Massachusetts Highway Commission, also spoke, urging the appointment of a committee with international scope to investigate the matter, this committee to have three members, an engineer, a lawyer and a business man.

Mr. J. de Pulligny, director of the French Mission of Engineers to the United States, gave a brief description of the methods under which the important public roads of France were constructed, and paralleled with it the lack of organization which is in evidence in America. He remarked that the admixture of engineering ability and financial backing required organization to ensure success in road building. He stated that the French unit of assessment is the square mile, that towns do their own maintenance, and that 90% of the present French system are township roads, upon which is spent 80% of the road funds. The old national roads we hear so much about constitute less than 6% of the present system.

The session on Wednesday morning opened with a paper by E. L. Cranford, road contractor, Brooklyn, N.Y., who dwelt upon the relation of the contractor, the engineer and the inspector to each other. In his address, he showed the frequent lack of harmony, and explained numerous methods of redress, expressing a clear conception of the functions of each official. Prof. A. H. Blanchard, of Columbia University, opened the discussion in a very appreciable manner, corroborating the general opinions expressed by Mr. Cranfield toward methods of making the relation and conditions more harmonious. Mr. H. W. Durham, Chief Engineer of the Bureau of Highways, Borough of Manhattan, N.Y.; Mr. F. E. Ellis, Manager of the Essex Trap Rock and Construction Co., Peabody, Mass.; Mr. Geo. S. Webster, Chief of the Bureau of Surveys, Philadelphia, and others continued the discussion, bringing out numerous suggestions worthy of due consideration for the improvement of conditions by intelligent co-operation.

A paper entitled "The Determination of the Amount of Re-alignment, grading and Drainage to be Done in Connection With Road Work" was read by Mr. S. D. Foster, Chief Engineer of State Highways, Pennsylvania. Among those who presented discussions were J. A. Johnson, Massachusetts Highway Commission; Mr. R. A. Meeker, Department of Public Roads, New Jersey, and Mr. J. H. MacDonald, Highway Commissioner, Connecticut. Another important paper was that by Mr. L. R. Grabill, Suburban Road Superintendent, Washington, D.C., who dwelt upon the factors covering the proper selection of road and street pavements.

Col. W. D. Sohier, Chairman, Massachusetts Highway Commission, in discussing Mr. Grabill's paper, emphasized the need of accurate traffic investigation and careful forecasting in future road improvement. He urged the adoption of an expense unit with traffic as a basis, suggesting the cost of maintenance per ton per mile over a unit width. He stated that the traffic in Massachusetts had doubled in two years' time, and that computation should be made with respect to the maximum traffic which will be encountered during the lifetime of the road.

Mr. W. A. MacLean, of the Ontario Public Roads and Highway Commission, gave a short address, outlining the work which the commission purposes doing in Ontario, and commenting upon the observations which have already been made through investigations. He suggested the method followed in England to secure stability of road foundation should be closely studied, and that roads in this country, after grading, be allowed a period of about three years of traffic in order to obtain natural settlement before road metal and surfacing be applied.

Papers giving details of construction of various types of roads and pavements were read at Thursday's session. Mr. Lynn White, Chief Engineer of the South Park Commissioners, Chicago, read a paper entitled "Bituminous Macadam and Bituminous Concrete." Other papers were "Earth Roads," by E. A. Kingsley, State Highway Engineer of Arkansas; "Sand-Clay Roads," by E. J. Watson, Commissioner, Department of Agriculture, Commerce and Industries, South Carolina; "Gravel Roads," by G. W. Cooley, State Engineer of Minnesota; "Concrete Roads," by E. F. Rogers, State Highway Commissioner of Michigan; "Birch Roads," by J. M. McCleary, Engineer, Cleveland, O.; "Wood and Asphalt Block," by H. H. Schmidt, Chief Engineer of the Bureau of Highways of Brooklyn, N.Y.; "Waterbound Macadam," by J. W. Hunter, Deputy State Highway Commissioner of

Pennsylvania; "Sheet Asphalt," by George H. Norton, Deputy Engineer Commissioner, Buffalo, N.Y.; "Granite Rock," by R. H. Gillespie, Chief Engineer of Highways, Borough of The Bronx, New York City.

Another paper which brought forth much open discussion was read by Mr. H. C. Hill, Meriden, Conn., who spoke concerning unit price and lump sum contracts and percentage work.

Thursday afternoon was taken up by an automobile trip over the different types of recently constructed roads and pavements including the inspection of the Philadelphia Service Test Roadway, which is built of twenty-six separate sections, with each section constructed of a different road material.

Prevost Hubbard, Institute of Industrial Research, Washington, D.C., read a paper on Friday morning entitled "The Testing of Materials for Road and Street Construction." Another important paper was "Sub-Organization for Securing Efficient Maintenance," by Mr. J. M. Carlisle, State Highway Commissioner, New York. These two papers, together with their discussion, constituted the entire session. In the afternoon Mr. A. W. Dean, Chief Engineer, Massachusetts Highway Commission, who spoke on "General Methods of Repairs and Renewals," and Mr. W. H. Connell, Bureau of Highways and Street Cleaning, Philadelphia, on "Bituminous Surface Treatment and Dust Prevention," presented very instructive papers, which called forth a good deal of discussion. These were followed by reports of committees, etc.

A synopsis of each of the papers read will appear in *The Canadian Engineer* at an early date.

CONCRETE ROAD CONSTRUCTION.*

By A. N. Johnson,
State Highway Engineer, Illinois; Springfield, Ill.

OWING to the nature of a concrete pavement there are involved in its construction certain principles quite different from those entering into the design of most other pavements. The fact that a concrete pavement consists of large slabs of rigid material, having a coefficient of expansion due to temperature changes very nearly that of steel, demands provisions for such changes.

As a concrete pavement possesses far less resiliency than most other street pavements, the stresses from traffic loads are greatly increased. This is particularly true of the blows delivered to the surface of the pavement by heavy horse-drawn traffic. Moreover, as all the surface is liable to receive such stresses, it is necessary that every portion of it shall be equally well constructed. It is, therefore, of first importance in the construction of a concrete road to have the greatest possible uniformity in the composition of the concrete. It is not only necessary that each batch of concrete shall have the requisite amount of cement and properly proportioned aggregate, but that every portion of each batch shall be so deposited in the road as to be as nearly uniform as possible.

Again, owing to the brittle character of the concrete, it is evident that depressions in the foundation causing a settlement of the pavement will be manifested by cracks, while such depressions occurring in a pavement of more resilient character, as for instance in most all forms of macadam construction, may not cause any serious break in the surface. Therefore, the utmost care should be taken to provide proper drainage for the foundation soil, perhaps even more care than in many other forms of construction.

Joints.—A concrete pavement is to be regarded as constantly moving. As the temperature increases, the pavement lengthens and with a fall in temperature it shortens. It is evident that provision for these variations must be made in the design of the pavement. Likewise it has also been shown by recent investigation that the absorption of moisture induces an increase in the bulk of the concrete, while the loss of moisture produces a shrinkage from which it will be readily appreciated that climatic changes introduce very complex conditions.

To prevent formation of cracks in a concrete road, in a haphazard way, joints must be arbitrarily placed in the pavement at the time of construction. As every joint in the pavement is a source of weakness, which the traffic will detect and which will afford an opportunity for moisture to penetrate the foundation, it is highly desirable to make as few joints as possible.

If the coefficient of friction of the concrete with the soil is assumed as unity, a slab of concrete 25 ft. long may be pulled over the foundation without exceeding 20 or 25 lb. tensile stress. Therefore, if expansion joints were placed every 50 ft., the centre of the slab, as the slab contracts, would develop a stress in the concrete within allowable limits.

If a crack, due to shrinkage that occurred in the pavement, remained compressive, that is, if it did not subsequently become filled with grit that would prevent the crack from closing as the pavement tended to swell, either from a higher temperature or absorption of moisture, there would be no great necessity for providing beforehand for expansion joints. This is based on the fact that concrete as it sets is observed to shrink an amount about equal to its expansion due to a change in temperature of 70° Fahrenheit, and the small shrinkage cracks which occur offer sufficient room for subsequent expansion of the pavement due to any expected rise of temperature.

But the joints will not remain free of grit, with the result that compressive stresses of over 1,000 lb. per sq. in. may be developed which are sufficient to buckle the comparatively thin slab of a concrete road. It is therefore important that expansion joints be provided and, moreover, that they be constantly maintained so as to be always compressible, which requires that they shall be filled with a plastic material, either a suitable coal tar or asphaltic pitch.

Various devices for the construction of expansion joints have been tried. In some cases ordinary wood paving blocks have been laid, on the theory that the shrinkage of the wood blocks in dry hot weather would provide sufficient room for the expansion of the concrete and that in cold weather, usually wet weather, as the concrete contracts the wood blocks will swell and the joint will remain filled. Steel plates, cut to the shape of the crown of the road, have been manufactured, with which each edge of the joint is lined, the space between the plates being filled with pitch.

It should be observed that there is very likely to be some unevenness at the joints, due either to faulty construction or subsequent wear, so that it is desirable, if traffic is to be inconvenienced the least possible, to place

*Paper presented before the Permanent International Association of Road Congresses, London, 1913.

the joints at other than 90° with the centre line of the pavement. An angle of 60° with the centre line of the road has been successfully used and found to add much to the comfort of traffic.

Materials.—Attention has been called to the fact that every portion of a concrete road should be of a high-grade concrete and also uniform. Many failures of concrete roads, due to raveling under traffic, may be explained by a lean mixture or a lack of uniformity. If a successful concrete pavement is to be laid, a concrete rich in cement must be used. It is evident that the strength of the pavement to resist the action of traffic depends upon the strength of the matrix or mortar in the concrete, assuming a proper aggregate has been employed. Also, if each particle of the aggregate is to be held in place, it is necessary that there shall be a sufficient amount of matrix entirely to surround each piece. To accomplish this purpose, it is first necessary that the mortar be rich in cement and second that the concrete be rich in mortar. probably quite as many failures have been due to a lack of mortar in the concrete as to a lack of cement in the mortar. If every particle of aggregate is to be surrounded by mortar, there must be mortar in excess of the voids in the coarser aggregate. Therefore, if failures have occurred with mixtures providing but 50% of mortar, as would be the case, for example, in a 1:2½:5 or 1:2:4 mixture, no great advantage would be gained by merely increasing the amount of cement and leaving a deficiency of mortar, for example, substituting for the above mixtures a 1:1½:3. A mixture that increases this proportion of mortar should generally be used; a 1:2:3½ mixture may be recommended.

Each batch of concrete must be thoroughly mixed and, as it is deposited in the road, great care should be exercised that the mortar does not flow to the edge of the pile and leave a core of aggregate with insufficient mortar. This is quite likely to happen and must be remedied by workmen who should be provided with rakes or shovels to distribute any such nests of aggregate. A little care and watchfulness will entirely obviate any difficulty from this source.

The nature of the aggregate will determine the wearing qualities of a concrete road. It is therefore important that only hard, sound materials be used for this purpose. In general, limestones and similar soft rocks are not to be recommended, while quartzitic or flint gravels afford widely dispersed sources of excellent materials.

Drainage.—It has been observed on some concrete roads that longitudinal cracks had occurred which are thought to have been due to the seepage of water under the outer edges of the concrete slab, thereby softening the foundation and causing a movement of the concrete slab by frost action. To prevent this, it is recommended that a shallow trench about the width of a shovel be constructed under each edge of the pavement, this trench forming a blind drain to be filled even with the subgrade with some coarse material and that lateral blind drains be placed from 40 to 50 ft. apart across the shoulders of the road, these cross drains extending from the longitudinal drains to the gutters or side ditches thereby preventing any seepage of surface water under the edge of the pavement in the foundation.

Two-Course Construction.—Many concrete pavements have been constructed in two courses, using a leaner mixture for the lower course and a richer mixture for the wearing surface. Evidently, this is an economical arrangement and would be recommended were it not for the unsatisfactory results obtained due to the fact that at the junction of the two classes of concrete there is developed a horizontal plane of weakness which would be caused by even a comparatively short delay in applying the top course. Under exposure to the hot sun, whereby the surface of the pavement becomes of a higher temperature than the lower portion, there is a tendency for the pavement to become slightly convex on the upper or wearing surface. If there is a horizontal plane of weakness near the convex surface, the upper layer of the pavement may become separated from the lower layer. And this has actually occurred. Soon after this takes place, the surface cracks under traffic and rapidly deteriorates. Therefore, unless some method can be found by which the top layer of rich mixture can be deposited simultaneously with the leaner mixture of the lower course, it is recommended that the whole pavement be made of uniform quality throughout equal to that desired for the wearing surface.

Curing the Concrete.—A most important part of the construction of concrete roads, and one that has been very often neglected, is a proper protection for the concrete while setting so that there will be no lack of moisture at this time. As soon as the concrete is a few hours old it should be covered with canvas which is kept moist. This canvas is to be replaced by a layer of earth which should be kept well wet for a period of ten days to two weeks.

Crown.—A concrete road requires perhaps less crown than any other form of paving surface, scarcely more than the eye would demand for appearance sake. One-eighth to one-quarter inch per foot will be found sufficient.

For convenience in construction, the roadbed may be made practically level and, it is evident, should be constructed with considerable care so that it does not become necessary to fill depressions in the roadbed with expensive concrete. The crown may be given by making the roadway slightly thicker at the middle than at the sides.

Thickness.—A thickness of 6 to 8 in. for the concrete seems sufficient for all ordinary conditions. On roads 20 to 24 ft. in width, and average of 7 in. may be used with 8 in. at the centre and 6 in. at the sides.

A form of construction that may prove desirable, where the greatest economy must be exercised, would be to provide a comparatively narrow strip of concrete at the centre with a good macadam construction for the shoulders. This would answer for those roads where the traffic at a given time of day is nearly all in one direction. Under these conditions a strip of concrete 10 to 12 ft. wide at the centre would take practically all the wear while the narrow strip of macadam at either side, 3 or 4 ft. in width, would suffice for the occasional passing of vehicles.

This character of construction is particularly applicable to a vast mileage of highways in America where such an enormous percentage is merely earth roads and where at present the maximum length of roads at the lowest cost possible is of the utmost importance.

Finish.—A concrete road should be left slightly rough as would be effected by a wood float. The templet which is used to give the shape to the surface of the road can be so devised and handled as practically to give the desired finish to the surface with the possible exception of here and there a slight imperfection which should be remedied by men with hand floats working from a lightly constructed bridge thrown across the road. It is highly desirable, however, that as little as possible be left to the

hand finishers as there is inevitably a tendency on their part to work slight depressions in the surface of the concrete which can scarcely be detected until the concrete has set and it is too late to afford a remedy.

Conduct of Construction.—The actual work of construction consists mainly of two parts: First, the preparation of the roadbed and hauling of materials thereon in such quantities as may be needed ready for the mixed. Second, placing the concrete and trimming the road sides.

The mixer used should be of a type especially adapted for this work, one which will move under its own power along the road as the work progresses and provide convenient means for handling the material onto the road.

Attention is called to the fact that the success of the road primarily falls upon the second portion of the work, which, however, involves but 9% of the total cost. It is suggested, therefore, that the public department having in charge a considerable mileage of this construction could well carry it on under two divisions, allowing the first part of the work to be done by contract while the actual placing of the concrete should be done by day labor under the immediate supervision of the officials of the department, in this way securing with the least trouble and expense assurance of proper construction in every particular. The organization for placing the concrete is compact, easily controlled by one man and, moreover, this portion of the work moves along rapidly and uniformly, so that its cost from time to time should vary but little and can be estimated with precision.

Costs.—The difficulty of presenting cost data that would be of any very general application is fully appreciated. The following table is offered together with such general information as to conditions as may prove of some interest if not of actual value.

Estimate of Cost of 1 Square Yard of Concrete Road. 7 Inches Thick.

No profits or overhead charges included.

Labor ..... 25c. per hour
Team and driver ..... 45c. per hour

	—Length of haul—			
	½ mi.	1 mi.	2 mi.	3 mi.
Superintendent, watchman and miscellaneous labor	0.055	0.055	0.055	0.055
Shaping roadbed and trimming shoulders	0.083	0.083	0.083	0.083
Loading and hauling materials.	0.116	0.153	0.218	0.296
Mixing and placing	0.109	0.109	0.109	0.109
Cost of sand and gravel at $1.50 per cu. yd., f.o.b. destination	0.379	0.379	0.379	0.379
Cost of cement at $1.20 bbl....	0.364	0.364	0.364	0.364
Expansion joints spaced 50 ft...	0.025	0.025	0.025	0.025
Coal, oil and miscellaneous supplies for mixer	0.007	0.007	0.007	0.007
Forms and other lumber	0.005	0.005	0.005	0.005
Total	1.143	1.180	1.245	1.323

For a thickness of 6 in. a similar analysis gives total costs per sq. yd. for the various hauls as follows: ½mi., $1.003; 1 mi., $1.035; 2 mi., $1.091; 3 mi., $1.158.

In adopting concrete for a road surface, it should be borne in mind that if a hard rigid form of pavement is undesirable for the traffic to be accommodated, it will not prove satisfactory. For example, with a large amount of light, horse-drawn traffic some more resilient form of pavement would be found better adapted, but where a large amount of motor and heavy horse-drawn traffic is to be provided for, concrete pavements are proving satisfactory. There are experimental data at hand which seem to indicate a concrete pavement to be one of the most durable forms of construction that have been employed, and, under many conditions, the most economical.

The wide distribution of materials suitable for concrete makes this form of construction of the widest application and, in fact, in many areas where there is nothing but gravel deposits, poor for ordinary road purposes, a concrete road becomes the most economical and durable pavement possible. Moreover, it does not require exceptional skill on the part of the workmen, but may be successfully laid, under careful supervision, with any reasonably good labor.

CANADIAN CANAL TRAFFIC IN 1913.

In a report recently issued by the Department of Railways and Canals, Ottawa, it is shown that the total tonnage to pass through Canadian canals for the past navigation season was 51,319,426. Last year with the ending of the navigation season the figures showed that 46,952,605 tons went through Canadian canals, the figures for the 1913 season, therefore, making an increase over last year's figures of 4,366,821 tons.

It will be noticed that there has been a falling off in the tonnage handled by the Ottawa Canal. The decrease for this year over last is 26,912. However, the principal freight to pass through that waterway is sand and building material and therefore the decrease is attributed to the lesser demand by contractors. This is also the case where other waterways show a decrease as their traffic depends upon the demand made for sand and similar material.

The figures also show that the Rideau Canal has accommodated more traffic during the past season than the previous or any other year in its history, the increase this year amounting to 11,090 tons.

The figures for the season ending November 30th, 1913, with the increase or decrease over last year's are as follows:—

Canal.	Traffic, in tons.	Increase or decrease.
Sault Ste. Marie	42,022,609	2,920,815
Welland	3,545,984	726,973
St. Lawrence	4,275,863	823,400
Chambly	555,602	62,813*
Ottawa	365,438	26,912*
Rideau	171,223	11,090
St. Peter's	65,108	1,699*
Murray	180,576	11,605
Trent	55,728	21,384*
St. Andrew's	81,295	14,254*
Total	51,319,426	4,366,821

*Decrease.

"Vol III. of the Annual Tables of Constants and Numerical Data, Chemical, Physical and Technological," published by the International Commission of the Seventh and Eighth International Congresses of Applied Chemistry, is now in press and will be issued early in 1914. A descriptive circular with references to reviews of previous volumes may be secured on application to the University of Chicago Press, the American distributers.

BOOK REVIEWS.

Design of Plate Girders.—By Lewis E. Moore, B.S., C.E. A. M. Am. Soc. C.E., Mem. Western Soc. of Engineers; Associate Professor of Structural Engineering, Massachusetts, Institute of Technology. Published by McGraw-Hill Book Company, Inc., New York. 283 pages; 85 illustrations; 3 folding charts; 42 tables; cloth; size, 6 x 9 inches. Price, $3.00.

This book is the outcome of six years' experience in teaching the subject of Bridge Design and of practical railroad work and designing in a bridge company. The author has also had experience on the Massachusetts Railroad Commission.

His practical experience has led him to thoroughly appreciate the difficulties encountered by young designers, with the result that the work is exceptionally complete and will be found very useful to structural engineers.

The arrangement of the subject matter is logical, and the space devoted to the various parts of the subject bears a better proportion to their relative importance than is to be found in most books of this nature. The explanations of the formulæ used are very full and clear, and numerous examples of the results of faulty design give the reader an appreciation of girder design from a practical viewpoint such as is seldom obtained from a text-book.

A contribution on deflection by Prof. W. H. Lawrence, of the Massachusetts Institute of Technology, will be found at the end of the chapter on the Theory of Plate Girders. There is also incorporated in the book a very useful chapter by John C. Moses, of the Boston Bridge Works, on Shop Practice. In this chapter the reader is introduced to considerations which are of the utmost importance, and which are, in a great many cases, either unknown to the designer or lost sight of in the mass of purely theoretical knowledge which he uses in his design. A design of this kind produces either of two results. Firstly, if the engineering department of the bridge company awarded the contract is abnormally busy or undermanned, the design will be executed, as nearly as possible, in accordance with the plans supplied, and the cost of fabrication will be excessive. Secondly, the bridge company may, as is usually the case, redesign the structure (without weakening it) to conform to economical shop practice. In this event the new design must be checked by the original designer, and the cost of the design is more than it would otherwise have been.

In the last chapter is embodied a set of the general specifications of the New York, New Haven and Hartford Railroad, dated 1912. Most bridge designs in Canada are, however, governed by the specifications of the different railway boards.

The book also contains a useful set of tables.

Conservation of Water.—By Walter McCulloh, C.E. Published by Yale University Press, 135 Elm Street, New Haven, Conn.; 225 Fifth Avenue, New York City. 106 pages; 40 plates; cloth, 7 x 10 inches. Price, $2.00 net, postage 15 cents extra.

This volume constitutes the first of the series of memorial lectures delivered under the Chester S. Lyman Lectureship Fund, before the Senior Class of the Sheffield Scientific School, of Yale University, and is made up of five chapters with the following captions: Introductory, Basic Data Essential to a Comprehensive Study of Water Storage, Water Power, Water Storage for Water Supplies, Sanitation and Irrigation, and the Water Resources of New York State. The lectures cover the field of the use and storage of water in a broad and general manner. The book is not a text-book in any sense of the word, but affords a readable commentary on the salient features of water conservation. It is unfortunate that as no doubt the size of the book has been curtailed by the necessity of covering the work in five lectures, space should be given to descriptions of the power plants at Niagara, since these developments have all been described many times, both in the engineering periodicals and in recent text-books. The volume is very handsomely printed, the numerous illustrations give it a most pleasing appearance; and, altogether, it will form a desirable addition to the library of the hydraulic engineer or the student interested in conservation.

The Railways of Great Britain.—By Lord Monkswell, D.L. Published by Smith, Elder & Company, 15 Waterloo Place, London, S.W. 296 pages; 25 illustrations; cloth. Price, $1.50.

The table of contents, which extends through five chapters, covers almost every item of railway equipment, expenditure, working, financing, traffic, hotels, water communication, labor union problems, and, indeed, all the varied activities and details of management involved in the maintenance and working of a large, modern railway. The main headings include the East Coast, the Railways of Central England, the West Coast and the railways of the South and East. The author, Lord Monkswell, is the third Baron with that title, but the family name is Collier. He is a barrister by profession, who has made railroad operation a study, and has written very fully on "French Railways." His book on British practice, while not being technical in the narrow sense, yet contains a great deal of technical information. It is a general and comprehensive survey of the whole railway situation as it exists in the British Isles at the present time.

The author deals very frankly with the matter of railway competition. In many cases, he shows that where there is an assurance of very considerable traffic between two points, served by two or more lines, it is almost impossible to bring about any competition in the ordinary sense of the term The tendeny is to enter into an agreement whereby each line binds itself not to give more than such and such facilities to the public. In cases of this kind, the only remedy for the public lies in the Government imposing definite conditions in the interest of the people. Even then, tacit understandings are reached between the companies, and these understandings not only tend to suppress competition still further, but actually hinder the introduction of improvements. Notwithstanding all this, it is true that the railways of Great Britain are ahead of their continental rivals in the matter of public conveniences.

Pursuing this matter, under a different heading, Lord Monkswell says that if there are two things, above all others, which the public would thoroughly appreciate, they are decreased third class fares and increased speed. In 1888, when the race from London to Edinburgh took place, and in 1895, when the race to Aberdeen was on, some very remarkable locomotive performances were shown. The Caledonian Railway, working the passenger traffic from Carlisle to Edinburgh, were able to haul a train, on time all the way, with perfect ease. This was done with a "single" driver engine weighing 42 tons, of which 17 tons were on the driving wheels, and these had a diameter of 84 inches. The grate area was only 17 square feet, or about the size of an ordinary dining-room table. The engine, No. 123, was timed to run 100¾ miles in 112 minutes and surmount the "Beattock bank," a grade of 1 in 80 for ten miles and 1 in 75 for six miles. The daily performance of this engine, well within the booked time, produced a profound impression at that period, and all the more so, when it was apparent that her uphill work was better than her downhill performance. The designs of engines used on the Caledonian proved what can be done in the way of speed, but the timing of trains at the present day has not been kept up to the high level of promise inaugurated in the West Coast race to Scotland. At that time, however, the entire railways of Great Britain felt the impetus, and the speed of trains was accelerated all over the Kingdom, until, as our author shows, the paralyzing effect of "agreements" deadened and restricted the otherwise natural growth of improvement.

It has been held that high speed on long non-stop runs is expensive, and with this subject Lord Monkswell deals very fully. The average British railway manager believes that high speed is a good thing, but believes also that it is costly, and does not pay. How far the danger of misplaced switches or misread signals, enters into this view, Lord Monkswell does not say. The author, however, believes that accelerated service can be made to pay. High speeds cost more than slow speeds, but the corresponding advantages gained by selling the better article, i.e., rapid transportation, might easily put the balance on the right side of the ledger. As a concrete example he takes the 6.05 a.m. ex-Euston for Manchester, and shows in detail what effect altering its time of arrival from 9.35 to 9.05 a.m. would mean and what the cost of gaining this 30 minutes would be. Step by step he proceeds, and takes the difference in cost, if more powerful engines replaced those now in use, with increased outlay for up-keep, more fuel, more supplies, and even higher wages for driver and fireman. All the many etceteras are taken note of, and set down as money items required in gaining the half hour, daily on this train. On the assumption that the engines ran 40,000 miles between "shoppings," the increased cost would be 2½d. a mile. Adding to this, the extra expense in road maintenance, and that due to increased wear and tear of train, he says that even taking the most unfavorable view possible, that 5½d. a mile would be the limit of extra expense, and that the average, when other trains are considered, would probably be considerably less. In face of this, if the increased speed attracted six more third class passengers to travel, the railway would actually be making a profit.

Lord Monkswell does not leave the matter here, but offers several very pertinent suggestions as to how time could be saved on the run from London to Edinburgh. He does not merely say it can be done, but shows how. He cites instances of locomotive performance on the Nord, in France. He gives his own country credit for pre-eminence in long non-stop runs, and shows the saving that has been effected by the use of the Ramsbottom "pick-up" water-troughs. He advocates a serious trial of increased speed as a revenue producer.

In the matter of railway carriage design, the old stage-coach, modified to suit railway service, was long the model. The advent of Pullman cars showed what could be done when that model had been entirely abandoned. The Pullman car is not popular in Great Britain, as English travellers prefer the compartment system, and their desires must be met; but certain it is that, unpopular as the Pullman car itself is, yet its advent produced a very marked change in the whole spirit of British railway carriage design. The increased dead weight per passenger, which gradually came as a result of increased comfort for patrons is at the bottom of the heavier engine design, which naturally went hand-in-hand with the desire for comfort and speed.

Railway signals are dealt with when the London and South-Western is under review. The author believes that the British system of signals is the simplest and most complete now employed. He says: "Ordinary visual signals leave little to be desired in broad daylight; they are slightly less perfect at night, when color and not shape has to be depended on." This is, perhaps, a fairly accurate statement of the average man's opinion. We can only say that experts are here and there beginning to modify their views, and feel that "position" for day and "color" at night is not an ideal arrangement. The author may have this in mind, for in a footnote he remarks: "Possibly something may be done by means of flashlight signals to differentiate signals at night." The Great Western, he tells us, has experimented with cab signals, both audible and visual, which give a driver the correct indication of the position of any signal he is approaching. The L. and S.W. are successfully experimenting with a system of wireless train control which involves the automatic stop.

The whole of the goods traffic on all the railways is gone over in detail, and to those who know only our long, unbroken trains of bulk freight, such as ore and coal, the demands of British traffic will be a revelation. The whole of the goods traffic seems to us more like a magnified express business than legitimate freight handling. The small car has its uses over there, and its economies, and the heavy, high capacity box cars used in Canada would well-nigh be useless in Great Britain.

As science advances and inventions multiply the possible rivals of the locomotive are mentioned in this book. Electricity has now an established place of its own, and the tram-car has secured a field for its own activities which is no longer debatable. The possibilities of the turban principle are still remote as applied to the locomotive, while the Diesel engine, using crude oil fuel, may some day be applied to railway work.

The book as a whole contains a mass of most useful information, and, though we have touched on the locomotive side of it for the benefit of interested readers, yet we have

only given a sample of its interest and its scope. The book can be read with profit and pleasure by the financier, the lawyer, the business man and the technical student, and, indeed, by any intelligent man to whom the many phases of the railroad problem appeals. The facts presented are not complicated by tables and masses of statistics, but the whole story is written in easy, flowing, connected style, which gives to the many and diverse topics treated an interest and a value which is unique in semi-technical literature.

A Pocket-Book of Useful Formulæ.—By Sir Guildford L. Molesworth, K.C.I.E., Past-President of the Institution of Civil Engineers, M. I. Mech. E., Fellow of the University of Calcutta; and Henry Bridges Molesworth, M. Inst. C.E. With an Electrical Supplement by Walter H. Molesworth, M. I. E. E., M. I. Mech. E. Published by E. & F. N. Spon, Limited, 57 Haymarket, London, and Spon & Chamberlain, New York. Twenty-seventh edition, revised and enlarged; 800 illustrations; viii. + 938 pages; oblong 32mo.; leather; gilt edges. Price, $2.00.

Molesworth's Pocket-Book of Engineering Formulæ needs no more than a mention to engineers. Fifty years have elapsed since the first edition was published containing 220 pages. In this, the twenty-seventh edition, there are 944. The pocket-book has been thoroughly revised, and contains a valuable addition in an Aviation Section. The Electrical Section has been carefully revised, and its symbols brought in accord with the International Standard Notation. This little volume well deserves its name of "A Pocket-Book of Useful Formulæ and Memoranda for Civil, Mechanical and Electrical Engineers."

The Railway Goods Station.—By Fred. W. West. Published by E. & F. N. Spon, London, and by Spon & Chamberlain, New York. 192 pages; fully illustrated; cloth; 4½ x 7½ inches. Price, $1.50.

This volume, written as a guide to the control and operation of the railway goods station, supplies a good deal of much-needed information, and a number of suggestions on the main principles upon which the regulation and organization of a goods station are based. The author does not attempt to publish an exhaustive treatise on the subject, but the general information concerning the station itself, staff organization, office routine, and discipline, the checking of goods, etc., should be found instructive. Of course, there is the fact that the book deals specifically with English practice, and a good deal of it, therefore, would be found somewhat impracticable by Canadian station men.

Highway Engineering.—By Arthur H. Blanchard, C.E., A.M., Professor of Highway Engineering, Columbia University, New York, and Henry B. Drowne, C.E., Instructor in Highway Engineering, Columbia University, New York. Publishers, John Wiley & Sons, New York. 762 pages; 240 illustrations; 40 tables; 5 plates; cloth; 6 x 9 inches. Price, $4.50.

The subject-matter of this volume, according to the author's preface, is based largely on the courses of instruction given by them at Columbia University and upon their practice as highway engineers. It is designed not only as a text for students, but also as a reference for engineers.

The order of arrangement is good, the treatment of the various phases of the subject is clear and concise, the text is well supplied with tables, diagrams and half-tones, and the volume is a model of the printers' art. Of many of the illustrations it must be said that the authors have given considerable advertising to a number of those who furnished cuts of machinery, a thing which, in a treatise of this nature at least, is open to criticism.

Chapters X. to XV. inclusive are devoted to bituminous materials. The authors deal at some length with the nomenclature, sources of supply, properties, physical and chemical tests, and also, in the light of more recent investigations and practice, with the employment of the material in the various types of construction and maintenance. To this extent a contribution has been made to the literature in highway engineering.

Of the remaining chapters it must be said that the subject-matter has, in most cases, been fully covered by former writers, and that this part of the book is largely a work of compilation. The volume will, however, find a place both with the student and with the engineer.

PUBLICATIONS RECEIVED.

Canadian Society of Civil Engineers.—Bulletin No. 9, dealing with elections, Society affairs, accessions to the Library, etc.

Ohio State Board of Health.—Monthly bulletin for November, containing articles on subjects of interest in the field of public health.

Department of Customs, Canada.—Report for year ending March 31st, 1913, comprising tables of imports, exports and navigation, compiled from official returns, 656 pages.

The Red Iron Ores of East Tennessee.—Bulletin No. 10, of the State Geological Survey. Compiled by E. F. Burchard, geologist. A book of 170 pages, well illustrated by figures and maps and carefully indexed.

Production of Copper, Gold, Lead, Nickel, Silver, Zinc and other Metals in Canada during 1912.—A report of 86 pages by C. T. Cartwright, B.S., Assistant Mining Engineer, Mines Branch, Department of Mines.

Central Railway and Engineering Club of Canada.—Official report of the October, 1913, meeting. The 48-page pamphlet contains an historical paper on Compressed Air by P. McCabe, Toronto Railway Company.

Coal-Mine Accidents.—Bulletin 69 of the United States Bureau of Mines, compiled by Fred. W. Horton, dealing with accidents in the United States and in foreign countries; and making comparisons. A booklet of 100 pages, well tabled and illustrated.

Board of Highway Commissioners, Saskatchewan.—Annual report for year ending with Feb., 1913, containing reports of Bridge, Highways, and Accountants' branches; regulations of municipal highways, and Public Highways Act; 56 pages, well illustrated.

American Society of Testing Materials.—Proceedings of the 16th annual meeting, held at Atlantic City, N.J., June, 1913, containing committee reports, papers and discussions of the Convention. A volume of 1,140 pages, illustrated and supplemented by numerous plates.

Industrial Research in America, dealing with the orderly and sustained progress that has been made in scientific achievement. A 24-page booklet, comprising the presidential address of Arthur D. Little before the American Chemical Society at Rochester, N.Y., Sept. 9th, 1913.

Phase Compensation, with Special Reference to Single-Phase Motors.—By V. A. Fynn, Consulting Engineer, Wagner Electric Manufacturing Company, St. Louis, Mo., being an amplification of articles published severally in the "Electrical World" during July, 1913; 51 pages, 43 figures.

Canadian Railway Club.—Official proceedings of November, 1913, meeting. It includes a paper and discussion

on "The Conservation of Natural Resources through the Electrification of Railways," by G. P. Cole, M.Sc., Mem. A.I.E.E., Canadian General Electric Company, Toronto.

Safety in Tunneling.—An 18-page pamphlet, written by D. W. Brunton and J. A. Davis for the United States Bureau of Mines, comprising instructions to the superintendent, the foreman, and the miner, and containing a list of publications by the Bureau on mine accidents and methods of mining.

Possible Causes of the Decline of Oil Wells, containing suggested methods of prolonging yield. Issued by the United States Bureau of Mines, Department of the Interior, as Technical Paper No. 51. Prepared by L. G. Huntley. Comprises 32 pages, and contains a list of publications on petroleum technology.

Laws Relating to Liability of Employers.—Second interim and final reports by the Hon. Sir William Meredith, C.J.O., Commissioner. A 58-page publication, including the draft of an act to provide for compensation to workmen for injuries sustained and industrial diseases contracted in the course of their employment.

Portions of the Atlin Mining District, B.C.—Memoir No. 37, Geological Survey Branch, Department of Mines, Canada. Compiled by D. D. Cairnes. This book deals with the general character and geology of the district, and directs special reference to lode mining. It has 128 pages, with numerous photographic reproductions and maps.

Production of Iron and Steel in Canada during 1912.—Compiled by John McLeish, B.A., Chief of the Division of Mineral Resources and Statistics, Mines Branch, Department of Mines, Canada. This 40-page bulletin deals with iron ore, pig iron, ferro-products, steel, bounties, exports and imports of iron and steel goods for the year.

Geology of the North American Cordillera.—Report of the Chief Astronomer, Department of the Interior. A detailed report on the geology of the mountains crossed by the international boundary at the 49th parallel. This publication constitutes Volume III., and comprises 10 chapters in 300 pages, fully illustrated with plates and figures.

Relation of Manufacturer to the Patent System.—An extensive article by W. M. Grosvenor, dealing with the close inter-relation between patents and the development of modern industry, and maintaining that the subject does not receive sufficient consideration on the part of economists in the United States, advising, in conclusion, the appointment of a Patent Commission.

Psychological Aspects of the Problem of Atmospheric Smoke Pollution.—By J. E. Wallace Wallin, Ph.D., of the Mellon Institute of Industrial Research and School of Specific Industries, University of Pittsburg. A 46-page pamphlet, dealing with the pathology and the aesthetic aspects of smoke pollution. The third bulletin of the Institute on Smoke Investigation.

Provincial Board of Health of Ontario.—Thirty-first annual report, containing a résumé of the work of 1912, including reports of Provincial Medical Inspector; reports of Laboratories of the Board and official regulations. A 496-page book, illustrated, and including Bulletin No. 1, being a treatise on the design, regulation and action of slow sand filters, by F. A. Dallyn, B.A.Sc., C.E., Provincial Sanitary Engineer.

Pollution of Boundary Waters.—A preliminary report of the special committee of the International Joint Committee having supervision of the investigation relating to boundary waters' pollution. It contains a compilation of documents relating to petitions of the Erie and Ontario Sanitary Canal Company for permission to divert 6,000 second-feet from Lake Erie for the purpose of remedying the existing pollution of Niagara River.

Mines Branch, Department of Mines.—A summary report dealing with the work of the Branch during 1912, containing general report of Dr. Eugene Haanel, director, a report on the field work, chemical laboratories, statistical division, assay office, fuel-testing station, ore-dressing and metallurgical laboratories, etc. It contains 174 pages, supplemented by maps of the Yukon Mining Districts.

Tungsten Ores of Canada.—A report by T. L. Walker, M.A., Ph.D., Mines Branch, Department of Mines, Ottawa. A treatise on the metal and its uses, general geological occurrence of tungsten ores, their concentration. The bulletin includes data concerning the world's production, and enumerates in detail the location of the various ore bodies throughout the Provinces of Canada. An appendix deals with a comprehensive bibliography of Canadian tungsten literature.

Chrome Iron Ore Deposits, in the Eastern Townships of Quebec.—A Report by Fritz Cirkel, M.E., Mines Branch, Department of Mines, Canada. A 140-page book containing full information respecting chrome iron ore mines throughout Canada generally, and including several chapters upon the uses and technology of chromium and its compounds. An appendix contains notes by Mr. W. Borchers on the metallurgy of chromium. The report is supplemented by numerous plates, photographs and drawings.

Hydro-Electric Power Developments.—Bulletin No. 4966A of the General Electric Company, describing numerous Hydro-Electric installations, such as those of the Great Western Power Company, Stanilaus, Great Falls, Mississippi, Pennsylvania, Connecticut River, Utah, and other similar developments. The publication is well illustrated with transmission line equipment, lightning arresters, transformers, generators, alternators, and plans, etc., of power sites. The Canadian General Electric, Limited, Toronto, are the distributors.

Canadian Trade Index.—A directory of the manufacturers of Canada, classified according to the articles made. The 1913-15 edition, compiled and published by the Canadian Manufacturers' Association, Inc., Toronto. The index includes within its scope all reputable manufacturing plants doing more than a local business. It includes a good deal of general information in concise form concerning the kindred character that all business houses may be presumed to require. This is a noteworthy addition to previous volumes of the work. 6½ x 10 inches; 288 + 170 pages, advertising; cloth. Price, $3.00.

Diagram Giving Stresses in Beams.—By H. R. Thayer, assistant professor of structural design, Carnegie Institute of Technology, Pittsburg. Published by D. Van Nostrand Company, New York City. Size, 7½ x 11½ inches. Price, $0.20 net. This is a compact diagram whereby sizes of I-beams, steel channels, wooden beams, composite girders, etc., can be obtained with ease and comparative accuracy. From it may be speedily deduced stresses in a beam caused by a given load or moment, stress modulus required for given loadings and stresses, design of beam for given stresses and loads or moments. It will be found a valuable time-saver in designing offices and remarkably comprehensive in its service.

CATALOGUES RECEIVED.

Apollo-Keystone Copper-Bearing Steel Sheets.—Published by the United States Steel Products Company, descriptive of this product, designed to resist rust. Full information respecting types, widths, etc.

The Concrete Roads of Wayne County.—A reprint of a paper presented by Ed. M. Hines, County Road Commis-

sioner, Detroit, to the National Association of Cement Users, distributed by the R. D. Baker Company, Detroit, Mich.

Pacific Type Locomotives.—Bulletin No. 1016, American Locomotive Company, New York City, containing tabular comparison of this type as built by that company for various roads. The bulletin is well illustrated, and contains general information that will be found of interest.

General Catalogue.—Robert Hudson, Leeds, England, manufacturer of portable railway plants, steel tipping wagons, locomotives, turntables, switches, crossings, rails, etc. Illustrating also a complete supply of contractor's plant, mining accessories. 70 pages, illustrated, and equipped with price lists.

The Milburn Light.—A handsomely printed 48-page catalogue published by the Alexander Milburn Company, Baltimore, descriptive of their portable acetylene lights for powerful out-door illumination. It contains a few pages on oxy-acetylene welding and cutting apparatus, as manufactured by the company.

Gears and Rolling Mill Pinions.—An 8-page pamphlet published by the Mesta Machine Company, Pittsburg, containing interesting data respecting gears in heavy mill machinery, and charts for determination of the dimensions of moulded gears for cast-steel. A section of the catalogue is also devoted to cut gears.

Steam Water and Air-Flow Meters.—Bulletin No. A4157. Canadian General Electric Company, Limited, Toronto, showing illustrations descriptive of accessories, parts, and installations of these products. Contains tables of pipe fittings, plugs, reducers, etc., and diagrams of dimensions of orifice tubes for measuring steam, air or water flow.

Baker Armored Concrete Pavement.—40-page illustrated catalogue, published by R. D. Baker Company, Detroit, Mich., descriptive of their armored plate to take care of expansion in concrete pavements. The catalogue also describes their installation bar. It contains interesting data about pavement materials, and includes specifications for laying concrete pavements, using the above appliances.

Hoisting Accessories.—A well-illustrated, carefully compiled 28-page pamphlet, being Bulletin No. 1805, Mining Machinery Department, Canadian Allis-Chalmers, Limited, Toronto. It is descriptive of cages and skips, landing-dogs, wire rope, sheaves, differential drums, safety hooks, mine and scoop cars, ore bins, and bin gates, etc. Photographs, line diagrams, charts and tables of strengths, weights, dimensions, etc., make this catalogue one that will be well appreciated.

ENGLISH CHANNEL TUNNEL POSSIBLE.

At the first Franco-Prussian Travel Congress, held in London the latter part of November, 1913, Sir Francis Fox, the engineer, gave an address explaining how the channel tunnel may be, and probably will be constructed between England and France. Sir Francis Fox and his partners agree that the enterprise is one that can be carried out with certainty, and at a comparatively moderate cost, the geological and other conditions being of exceptionally favorable character for the construction of a submarine tunnel. The English company would construct the double-barrelled tunnel from Dover to a point in mid-channel, and the French company would construct the other half from Sangatte. Borings would be made through the lower, or gray chalk, which is practically free from and remarkably impervious to water. This chalk bed is eighty-seven feet thick at Dover and eighty feet thick at Sangatte. Its ingredients are very similar to the components of Portland cement. It is an excellent material to work in as it "puddles" itself and becomes impervious. Sir Francis pointed out that protective works might be constructed similar to those introduced by the French, Swiss, and Italian military authorities in connection with the Alpine tunnel from the "food-supply-in war-time" point of view. "Finally, we ought emphatically to dispel a fallacy which seems to have arisen in connection with the earlier proposals," he said, "namely: that in case of war it would be necessary to blow up or permanently destroy this great work of a channel tunnel. Both in the English and the French portions the level of rails has been so arranged that, by the simple process of opening some valves—which will be under the control of the military authorities, and within the lines of fortification at Dover—a sufficient volume of water could be admitted to fill the tunnel to its roof—for a few hundred yards. This would eventually block the tunnel without injuring it." He estimated that the "drainage heading"—a smaller boring in advance of the main boring—could be driven through the chalk at the rate of seventeen yards a day, or three miles a year each way, making a joint progress of six miles a year. It would thus take four years to complete the drainage bore, and the entire work might be completed in a little over six years. Each tunnel would, when completed, consist of a cast-iron tube, "grouted" on the outside with cement, and lined inside with concrete in cement, so as to make a smooth surface and prevent corrosion.

FILTER PATENT SUIT DECIDED.

A decision has just been rendered at Cincinnati sustaining the patent of J. C. W. Greth, for Water Purifying Apparatus described by claim 11, of that patent, as follows:—

"In continuous flow water purifying apparatus the combination with a single tank containing the chemical reacting compartment, and an upward flow settling compartment of a series of independent gravity filters carried on the top of the tank, fed by overflow from the settling compartment, and each having means for washing the filter and a valve to close communication with the settling compartment, whereby any one of said filters may be isolated and washed, while the flow continues through the others from said supporting tank."

The suit was originally filed at Louisville, Ky., in 1910, by Wm. B. Scaife and Sons Company, of Pittsburgh, Pa., against the Falls City Woolen Mills. The district court denied the injunction and appeal was taken with the above result.

Under the ruling of the Court in this case, it would seem that there would be no way to use plural, or continuously washable—without interrupting—filters in any continuous system in the United States. Greth having been the first to devise such structure, or, as the Court says, near the end of its decision:—

"The idea of a group of filters, each of which could be cut out independently, without affecting the work of the others was broadly old, but had been applied nowhere except in city water supply systems or for analogous uses where the lake, river or pond was the settlement basin and the water was brought therefrom in conduits to the filters. It had never been applied as a part of a unitary structure in the treatment of water to produce a comparatively small continuous flow for industrial purposes. When so united with such a structure, in a compact unitary well designed and effective form, it makes a new combination, and it produces a result different from what had before been accomplished."

COAST TO COAST.

Chatham, Ont.—It is announced that the Chatham water commission has a surplus of $5,834 for the past year.

Calgary, Alta.—The gross earnings of the Calgary municipal street car lines were $60,670, and the expenses about $1,000 less than this figure.

Vancouver, B.C.—Station work is now proceeding on 28 miles of the 38-mile section of the Hope Mountain railway which is being constructed through the Coquahalla by the Kettle Valley Railway, for the joint use of the V.V and E. and the K.V.

Winnipeg, Man.—Winnipeg's hydro-electric system continues to show steady progress and the record was obtained during November, when apparent net earnings amounted to $79,677.35 after making all allowances for discounts, possible bad debts and so on. This is an increase of $7,645.27 over the preceding month.

Ottawa. Ont.—The latest available information gives the total appropriation for improvements to the harbors of Canada as $28,214,000. The work, which involves harbor dredging and river work, has occupied the main attention of the public works department during the past season. Of the amount appropriated, $17,000,000 will represent practically the amount spent by the end of the present fiscal year.

New Westminster, B.C.—The department of public works does not contemplate letting any more contracts during this year. This is because the work provided for in the 1913 estimates is now either completed or under way and any new works will have to come under next year's estimates. Since the federal house does not meet until January it will be at least March or April before the department of public works' estimates have been considered.

Stratford, Ont.—At Stratford the Grand Trunk Railway Company has constructed and officially opened a $50,000 new station. The new station is said to be one of the finest on the road, and will also house the divisional headquarters. It is built of brick, with Roman stone facings, and has a frontage of over 150 feet. New additions were also made to the yards, and new freight sheds were erected.

Peterborough, Ont.—One hundred arc lamps have recently been installed at Kingston by the Hydro-Electric Commission at a cost of $120,000. The new light and power system has been switched on, and has so far proven satisfactory. The wires for the street lighting have been placed underground; and in the down town district, the few poles necessary will be placed in the rear of the buildings.

Port Arthur, Ont.—For the year 1913, the electric department in Port Arthur showed a net profit of $62,000, or a gross profit of $165,700. At present the city is using 2,100 horsepower from the Hydro-Electric Commission, and 700 horsepower from the Current River station. The present storage capacity of the various dams in the system is 1,843,100,000 cubic feet, and water this fall was running over all which was an unprecedented condition for this time of the year.

Ottawa, Ont.—By the middle of January, the report being made by officials of the Canadian and United States Governments on the serious pollution of international waters extending from the Lake of the Woods to the St. John River, will be before the International Joint Commission. The examination made so far is complete except with regard to the St. John River, where some further work has to be done. The report of the engineers who have been taking the levels of the Lake of the Woods will also come before the commission at the same time.

Fredericton, N.B.—Development in railway facilities in New Brunswick, and particularly in Fredericton and its neighborhood, has been decidedly marked during the past few years. When the several lines of railway now under construction are finished and in operation, and some other lines now in contemplation have also been built and are in operation, no country will possess more or better transportation facilities than New Brunswick. Within a very short time, a railway will be in operation in practically every settled portion of the province; and the days when the farmer is compelled to drive many miles by team in order to reach a market town, will soon be a thing of the past.

Montreal, Que.—According to the statements of J. G. Sullivan, chief engineer of the western lines of the C.P.R., that company has had under construction this year a grand total of 1,700 miles of railway west of Fort William. The amount of work which has been handled by the construction department of the company this year represents more material than was moved during any period in the construction of the Panama Canal and represents no less than 30,000,000 cubic yards. In regard to the grading of new lines this season, the total work accomplished amounts to 557 miles of new line, exclusive of sidings and terminal work and 262 miles of double-tracking on the main line.

Ottawa, Ont.—Doubts which have been entertained concerning the harbor possibilities of James Bay, have been dispelled by the summer investigation of the hydraulic surveys, conducted under the auspices of the Naval Service Department. These have led to the conclusion that first-class harbor facilities are to be found in James Bay in the vicinity of the mouth of the Nottaway River. Good shelter, ample room, and a sufficient depth of water have been found, and very little silt is in evidence to necessitate dredging. Soundings indicate plenty of water right out into the bay. Examination of conditions at the mouth of the Moore and Rupert Rivers shows that they are out of the question as harbor possibilities. Ice conditions will, of course, have to be contended with in James Bay, but the difficulties in this connection are by no means insurmoutable for navigation.

Galt, Ont.—The report of the local Hydro-Electric Commission shows, during the past 11 months of the present year, 434 new subscribers, which will doubtless be increased in December to 475. During 1912, there were but 347 new applications for service. The capital investment of the commission is now $177,936.76 and the total increase of this account for the present year is $47,946.90, of which $25,028.74 is for ornamental lighting. The work on installing ornamental lighting this year has been very extensive, 23 miles, 184 feet of cable being laid and 252 lighting standards placed. Galt to-day has more ornamental lighting than any place its size in Canada and still has a number of streets to be supplied for which petitions are now in hand. The total cost of operation including sinking fund and interest for the 11 months of the present year is $30,463.30, while the revenue for the same period amounts to $40,509.32, leaving a gross profit of $10,046.02. The increase of business of the department is better illustrated by the increase in the connected power load of 750 horsepower one year ago to 1,103 horsepower at the present time. Galt is now paying $21.50 per horsepower.

Barriefield, Ont.—It is expected that by Christmas the new Barriefield station of the Marconi Wireless Telegraph Company of Canada will be almost complete. The two masts at Barriefield are 450 feet apart, and 185 feet high. The cross-arms are 20 feet wide and are used to space the aerial wires. The aerial, in this case, will take the form of the letter "T" so as to radiate and receive equally in all di-

rections. There will be two gasolene engines, of eight horsepower each, and two special high frequency generators. These travel at a speed of 200 revolutions a minute. Mr. Edwin E. Robinson of the technical engineering staff of the company reports the situation at Barriefield as ideal, and expects to send one of the first messages to Midland, about 100 miles north of Toronto. The Barriefield station will give out a musical note when messages are being transmitted, probably about middle "C" on the piano. This is accomplished by a disc which has a number of points passing very close to two fixed points at a very high rate of speed. There will be in the neighborhood of 100,000 volts on the aerial. Around the outside of the operating house is buried a quantity of copper netting and zinc plates. This is to act as a return circuit to another station, the air being used in place of wire.

Toronto, Ont.—This year Toronto has acquired four continuous stretches of good roadway, which the city has not known before. Since Yonge Street has been repaired, there is a splendid straight road from Toronto Bay to York Mills, a distance of seven miles at least. Since University Avenue has been newly paved, a splendid connection of about six miles of roadway has been afforded along that avenue to College Street, west on College to St. George Street, north throughout the length of St. George to Dupont Street, west on Dupont to Spadina Road, north on Spadina to Davenport Road, west on Davenport to Walmer Road, north on Walmer to Theodore Road, west on Theodore to Bathurst Street, north on Bathurst to St. Clair Avenue, and thence along St. Clair to Prospect Cemetery and West Toronto. The third roadway connection, which is about seven or eight miles long, follows University Avenue to Anderson Street, west along St. Patrick Street to Bathurst Street, and thence west on Arthur and Dundas Streets through West Toronto to Lambton. The fourth follows east along Wilton Avenue, crossing the Wilton Avenue bridge, and along the Wilton Avenue extension beyond Broadview Avenue to Bolton, north on Bolton to Gerrard Street, along Gerrard to Logan Avenue, north on Logan to Danforth Road, and finally along Danforth to East Toronto and the Kingston Road.

PERSONAL.

CLARENCE W. NOBLE, contracting structural engineer, Toronto, who has been on a trip throughout the Canadian West during the past five weeks, is expected to return next week.

J. E. GRIFFITH of the British Columbia Civil Service, and previously associated with the construction department of the Canadian Pacific Railway west of Winnipeg, will, it is announced, succeed W. W. Foster, resigned, as Deputy Minister of Public Works for British Columbia.

R. H. CUNNINGHAM, B.A.Sc., has been appointed manager of Canadian Hoskins, Limited, Walkerville, Ont. For several years Mr. Cunningham was connected with the Hoskins Manufacturing Company of Detroit, and received the above appointment upon the opening of the Canadian branch factory.

J. W. STEWART, of Foley, Welch and Stewart, railway contractors, has assumed the managing directorship of the construction of the Pacific Great Eastern Railway, now under construction from Vancouver to Fort George. This change was necessitated by the illness of Mr. Welch. The firm is striving to have about 1,100 miles of the road completed by next August, giving direct connection between Vancouver and Lillooet.

COPIES WANTED.

About six copies each of *The Canadian Engineer*, issues of July 31st and September 4th, 1913, are desired. We would be glad to advance by one month the date of expiration of subscription of any subscriber who may care to forward a copy of either of these dates from his own file.

VICTORIA BRANCH, CANADIAN SOCIETY OF CIVIL ENGINEERS.

The annual meeting of the Victoria branch, Can. Soc. C.E., was held on Thursday, December 11th, at the branch club rooms, 534 Broughton Street, when the following officers were elected for 1914—viz.:—

Executive—F. C. Gamble, chairman; D. O. Lewis, vice-chairman; A. E. Foreman, treasurer; R. W. Macintyre, secretary; E. H. Harrison and Lewis W. Toms. The auditors are H. A. Icke and F. A. Richardson.

The chairman gave a brief review of the work accomplished by the branch during the past year, and whilst advocating a change of officers from year to year, at the same time expressed his appreciation of being elected by acclamation to a third term in the chair.

Mr. J. B. Holdcroft, A.M., read an interesting paper, illustrated with diagrams, on the "Cellular design of vibrated concrete construction, with especial reference to its use in sub-aqueous work," which evoked an animated discussion between the members present.

STEAM TURBINES.

At the first regular meeting for the season, on December 19th 1913, Mr. J. A. MacMurchy of the Westinghouse Machine Company, Pittsburg, Pa., addressed the Toronto section of the American Institute of Electrical Engineers, on "Steam Turbines." The address was illustrated, and created much interest.

THE CENTRAL RAILWAY AND ENGINEERING CLUB.

The regular monthly meeting of the Central Railway and Engineering Club of Canada was held in the Temple Building, Toronto, on Tuesday, December 23rd. A very interesting paper was read on "Scientific Illumination," illustrated by lantern views, by Mr. J. W. Helps, late Industrial Engineer, Toronto Hydro-Electric System. Mr. C. L. Worth, Toronto, is Secretary.

COMING MEETINGS.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS.—Seventh Annual Convention will be held at Great Northern Hotel, Chicago, December 29th to 31st. Secretary, I. W. Dickerson, Urbana, Ill.

MINING AND METALLURGICAL SOCIETY OF AMERICA.—Annual Meeting will be held in New York City, January 13th, 1914. Secretary, W. R. Ingalls, 505 Pearl Street, New York.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

ORDERS OF THE RAILWAY COMMISSIONERS
OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20999—December 11—Authorizing C.P.R. to construct spur for Merchants' Trust and Trading Co., Limited, town of Nanaimo, Vancouver Island, B.C.

21000—December 11—Extending, until March 1st, 1914, time within which C.P.R. reconstruct culvert on Chalk River, Sub. Div., Eastern Div., bridge No. 53.2, near Arnprior, Ontario.

21001—December 9—Directing that, within 15 days after Applicant, G. A. Farrill, of Kenilworth, Ont., notifies C.P.R. that he has dug ditch "H. G." to right-of-way of fence at point "G," said Ry. Co. extend ditch on north side of crossing to right-of-way of fence, at point "G," and place at least six inches of gravel on farm crossing approaches.

21002—December 12—Authorizing C.P.R. to construct road diversion in Sec. 9-34-18, W. 3 M., Sask.; and construct, at grade, its Wilkie-Auglia Branch across said diversion at mileage 40.2.

21003—December 13—Authorizing C.P.R., to construct, at grade, its Snowflake Westerly Branch across road allowance between Secs. 14 and 15-1-11, W. P. M., Manitoba, at mileage 9.11 on said Branch.

21004—December 11—Amending Order No. 20878, dated Nov. 1st, 1913, by adding words, "except Sunday," after word "daily" and before word "passenger," in second line of operative part of Order.

21005—December 9—Amending Order No. 17522, dated 18th, 1913, by adding words, "in so far as it relates to Chemainus Road only," after "plan 'A,'" in second last line of operative part of said Order .

21006—December 15—Authorizing C.P.R. to construct siding for Canadian Bag Co., Limited, Montreal, Que., subject to certain conditions, and approving and authorizing clearances as shown on plan, subject to condition that men be kept off tops and sides of cars while operating said siding.

21007—December 10—Authorizing London and Lake Erie Ry. and Trans. Co. to connect with the M.C.R.R., for interchange of traffic between said Railways, just northeast of station in St. Thomas, Ont.; M.C.R.R. put in switch, at its own expense, and do work on its right-of-way, furnishing, free of cost, land therefor, as shown on plan; cost of remainder of work paid by London and Lake Erie Ry. and Transportation Co.

21008—December 11—Authorizing C.P.R. to construct sidings for city of Montreal, Que., at Mile End.

21009—December 11—Authorizing, temporarily, and until interlocking plant is installed, C.L.O. & W. Ry. (C.P.R.) to operate its trains across C.N.O.R. in Lot 27, Con. 2, Tp. Pickering: interlocking plant to be installed by June 15th, 1914; pending installation crossing be protected by flagmen, appointed by C.N.O.R. at expense of C.L.O. & W. Ry.

21010—December 9—Rescinding Order No. 17667, dated Oct. 4th, 1912, in so far as it relieves C.P.R. from fencing that portion of its right-of-way from mileage 29.5 to 32, east side, and mileage 29.5 and 31.5 on west side. 2. Directing C.P.R. fence said portion of right-of-way from mileage 29.5 to 32, on east side, and from mileage 29.5 to 31.5 on west side, on or before May 31st, 1914.

21011—December 15—Declaring that charge of thirty-four ($34) dollars for demurrage on shipments of coal, consigned to Canadian Coal and Commission Co., Bienfait, Sask., and shipped on 9th and 11th days of December, 1912, was illegal.

21012—December 11—Authorizing C.N.R. and C.P.R., pending installation of interlocking plant, to operate over crossing in N.W. ¼ of Sec. 16-52-24, W. 4 M., Alta., until June 15th, 1914, subject to condition that crossing be protected by flagmen, appointed by C.P.R., at expense of C.N.R.

21013—December 10—Authorizing G.T.P. Branch Lines Co., and C.P.R., to operate over crossing at Regina, Sask., without their first being brought to a stop.

21014—December 11—Approving plans, on file with Board under file with the Board under file No. 22913, showing G.T.R. Ry. Co.'s 88' 6" and 75' turntables.

21015—December 11—Authorizing G.T.R. to reconstruct abutments of bridge No. 63, mileage 152.51, carrying 20th Dist. of its railway over public road at Holmesville, Tp. of Goderich, Co. Huron, Ontario.

21016—December 13—Authorizing, temporarily, pending installation of interlocking plant at crossing, C.P.R. and G.T.R. to operate their trains over crossing in West Half of Lot 14, Con. 2, Twp. of Trafalgar, Co. Halton, Ont., at mileage 32.56 from Toronto, subject to condition that trains of both companies be brought to a full stop before crossing diamond.

21017—December 12—Authorizing G.T.P. Ry. to divert Government Road at mileage 212 west of Yellowhead Pass, Cariboo District, B.C.

21018—December 13—Approving revised location of G.T.P. Ry. main line through Chig-ni-Kath Indian Reserve, from mileage 125.55 to mileage 127.08, Range 5, Coast Dist., B.C.

21019—December 13—Authorizing G.T.P. Ry. to construct highway in N.E. ¼ Sec. 8-45-1, W. 6 M., Dist. North Alberta, Alta., at mileage 1028 West of Winnipeg, under its main line of railway.

21020—December 13—Authorizing G.T.R. to construct siding into the premises of the Lyster Wood Box Turning and Enamelling Co, on Cadastral Lot 16-A, original Lot 16, Rge. 5, Tp. Nelson, Co. Megantic, Que.

21021—December 15—Authorizing C.P.R. to operate its trains over bridge No. 0.85, on Temiskaming Branch, Lake Superior Div., Ont.

21022—December 16—Approving proposed location of C.P.R. shelter station on E. ½ of Lot 18, Con. 4, Tp. Asphodel, Ontario.

21023—December 10—Approving location C.P.R. station at Reeder, in S.E. ¼ of Sec. 19-13-27, W. P. M., at mileage 21.4 on Co.'s Virden-McAuley Branch.

21024—December 9—Approving further proposed alterations required to be made in C.L.O. & W. Ry. (C.P.R.) railway in order to accommodate extra tracks in Ry. Co.'s station grounds in town of Bowmanville, so as to include those portions of subdivisions Lots 3, 5 and 6, Block 2 of said town.

21025—December 12—Approving Supplement No. 1 to Express Classification for Canada No. 3, amending and superseding Section 2 of Article T of Tariff of Rates on Money, Securities, etc.

21026—December 15—Approving revised location C.N.R. spur for Thomson, MacDougall and Company, Woodlands, Man., through Sec. 18-14-2, and Secs. 13 and 11-14-3, W. P. M., Man., from mileage 3.38 to 4.92; and authorizing the construction of said revision over two (2) road allowances,—1, Secs. 13 and 12, and 14 and 11, Tp. 14, R. 3, W. 1 M., and 2, Secs. 13 and 14, and 12 and 11, Tp. 14, Rge. 3, W. 1 M.; and rescinding Order No. 19970, dated Aug. 6th, 1913.

21027—December 5—Authorizing C.N.R. to open for traffic its line of railway from mileage 83 to Moose Jaw, in Prov. Sask., on its Radville-Moose Jaw Line, a distance of three miles.

21028—December 20—Requiring C.P.R. to extend to Ontario and Manitoba Flour Mills, Limited, privilege of milling all-rail grain at Sudbury, Ont., in transit from Port Arthur, Fort William, and points west thereof, at through rate to all points east of Sudbury, and the Detroit and St. Clair Rivers reached by millers west of Fort William under milling in transit arrangements, subject to regulations and restrictions thereof; and subject, also, to same additional toll of 1c. per 100 lbs. for terminal service at Sudbury, said rate to come into force not later than January 12th, 1914.

Barrett Specification Roofs

Low Cost—Long Service

Metal roofs require painting every few years, most ready roofings require coating regularly, but with Barrett Specification Roofs *there is no maintenance expense.*

Barrett Specification Roofs are roofs of coal tar pitch and tarred felt, with a top surface of slag, gravel or tile, *laid according to the Barrett Specification.*

This specification is simply the standard formula for building a first-class roof of this character.

It is possible, of course, to make an inferior roof of these materials either by poor workmanship or by using insufficient and poor goods. But if the Barrett Specification *is followed absolutely and the materials called for are used*, you are certain of getting the best value in roof coverings.

Such roofs usually last twenty years and over without leaks or repairs.

Barrett Specification Roofs are almost universally used on factories and buildings of large roof areas and where costs are carefully figured. They are equally good for city dwellings, warehouses, railroad buildings, etc.

Copy of the Barrett Specification, with diagrams, mailed free on request to nearest office.

McGill Building
Montreal, P. Q.

Architect: R. E. Bostram
General Contractor
C. E. Deakin
Roofers: Campbell & Gilday

Special Note We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding. If any abbreviated form is desired, however the following is suggested: ROOFING—Shall be a Barrett Specification Roof laid as directed in printed specification, revised August 15, 1911, using the materials specified, and subject to inspection requirement.

RAILWAYS—STEAM AND ELECTRIC.

+—College Bridge, N.B.—The Cabinet Council at Ottawa recently awarded to S. R. GOUDET and C. DUPUIS the contract for the erection of a station building and platform at College Bridge, N.B., at a cost of $4,300.

+—Kingston, Ont.—Orders have been recently received by the CANADIAN LOCOMOTIVE COMPANY for one saddle-tank locomotive for the British Columbia Equipment Company, Vancouver; two saddle-tank locomotives for the Confederation Construction Company, Welland Canal; one saddle-tank locomotive for the Union Carbide Company of Canada, Welland; six moguls for J. D. McArthur, Hudson Bay Construction Company. These contracts added to that of the extension of the government contract placed less than a month ago, will keep the company busy until next May.

Montreal, Que.—A new line under the title of the Hudson's Bay and High River Railway is under contemplation. British capital to the extent of two and a half million dollars has already been put into the projected line, through Southern Alberta, which will tap the coalfields west of High River and eventually connect with the western terminus of the Hudson Bay Company's line. At present preliminary survey lines are being run and parties are out in the field mapping out a route north and east from High Wood Hills at the foot of the Rockies, west of High River. Although no definite route has been decided upon, it is an assured thing that the road will be through the Okotoks and Black Diamond oil fields. The road will probably be opened as an independent line until the Hudson Bay line is extended westward through Saskatchewan and southern Alberta, when it will doubtless be taken over by the big company.

Montreal, Que.—With reference to a petition laid before the last meeting of the city council, asking to have the agreement with the Tramways Company carried out by laying the street car tracks along Van Horne Avenue to the western limits, the secretary informed the council that the company would commence to lay the tracks early next spring and the work would be pushed forward as quickly as possible.

Montreal, Que.—The Montreal Chambre de Commerce has been asked to interest its members in having a branch line of railway constructed from Montreal to Abitibi, to connect with the Grand Trunk Pacific railway.

Ottawa, Ont.—The Western Central Railway will apply to parliament at its next session for extension of time for the beginning of construction and for other railways to guarantee its bonds.

Ottawa, Ont.—The Norfolk and Elgin Railway will apply to parliament next session for incorporation. The proposed route is from Simcoe westerly through the townships of Woodhouse and Charlotte, southerly through North Walsingham, then southerly to the shore of Lake Erie, and from there to Port Burwell.

Ottawa, Ont.—The proposal now being negotiated with the Government, Sir Rodolphe Forget, Sir William Mackenzie, and others, is that the Quebec and Saguenay line be assisted financially in order to ensure completion, and that a joint arrangement be made whereby the Canadian Northern, the Grand Trunk Pacific and the C.P.R. would have running rights over it from Quebec to the terminal at St. Catharines Bay, the entrance to the Saguenay River, which is proposed as a St. Lawrence winter port.

Ottawa, Ont.—The agreement has been signed by the Hon. Frank Cochrane, which will enable the commencement of the immense terminal undertakings in Quebec. They involve the division between the Grand Trunk Pacific and Canadian Pacific for the construction of a union depot and also a freight depot, extensive car shops at St. Malo, and a large freight yard at St. Foye. A tunnel is to be built between the Union Station and the one on the harbor front. The negotiations of the government involve the purchase of three miles of waterfront at Quebec at a quarter of a million dollars.

Saskatoon, Sask.—As a result of the action of the city council recently, the Radial Line from Saskatoon will be taken over and operated as soon as orders-in-council can be secured authorizing this city to operate the line. The government will be requested to pass the necessary orders.

St. John, N.B.—Plans have been filed at the registry office for the construction of a spur line about two miles long from the I.C.R. branching from the main line beyond the One Mile House in the Marsh Road, and crossing through the Old Marsh Road to Kane's Corner, and from there diagonally across to Courtenay Bay at the foot of Edgeburt Street, and thence across on trestle to the foot of Union Street, where it joins the old Courtenay Bay spur.

Toronto, Ont.—Nothing further will be done this year in the proposed Municipal Hydro-Electric Railway, but a conference between the commission and representatives of the municipalities will be held early in January. All the surveys

MANNESMANN

SEAMLESS AND LAPWELDED

STEEL TUBES

Our tubes can be bent cold on the spot without trouble.

Our tubes can be supplied in lengths up to forty feet, thus effecting a large saving in joints, jointing material and labor.

Leakage is reduced to a minimum, as the joints are far tighter and seventy per cent. fewer.

Saving in freight, etc., is considerable, as a steel tube weighs one-third to one-half as much as a cast iron pipe of the same length. And there are other convincing reasons and illustrations in our booklets.

BOOKLETS ON REQUEST

MANNESMANN TUBE CO., LIMITED 51 Victoria Square MONTREAL

and collection of data have now been secured, and it is probable that a definite scheme will be outlined at the January meeting.

+—**Westville, N.S.**—The Ottawa Cabinet Council recently awarded to MESSRS. McLEOD AND SIMMS the contract for the construction of a freight shed at Westville, N.S., to cost $1,750.

GARBAGE, SEWAGE AND WATER.

London, Ont.—The London board of trade has appointed a sub-committee to consider the advantages and feasibility of separating the hydro and waterworks departments, which will report at the next general meeting of the board.

London, Ont.—The Trades and Labor Council has expressed itself as strongly opposed to the idea of the City Gas Company distributing natural gas in London, its chief reason being that the price that will be asked, if the by-law carries, is considered by many to be almost prohibitory.

London, Ont.—A meeting of the London Board of Health will consider the matter of the distribution of natural gas in London without its being purified before entering the city mains. Should the board insist upon the purification of the entire supply, the agreement may have to be declared cancelled as an economic impossibility; for it would then be impossible to use the gas for fuel purposes.

New Westminster, B.C.—Sufficient names have been secured to a petition, the result of which will be that the by-law for the gas plant purchase will be resubmitted to voters. The city council has handed over the petition to the assessment commissioner for inspection.

Ottawa, Ont.—The Economical Gas, Light and Power Company, of Montreal, which offered a short time ago to instal at Ottawa a gas plant which would supply gas at 75 cents a thousand for lighting and 60 cents a thousand for heating, has announced that it is prepared to send at once to Ottawa an engineer to explain before the City Council the whole proposition.

Ottawa, Ont.—A meeting of the International joint commission will be held in Washington, beginning on the morning of January 13. The commission will consider the application of the Michigan Northern Power Company for authority to build a dam for power purposes at Sault Ste. Marie; also the application of the Greater Winnipeg Water district to divert water from Shoal Lake, west of the Lake of the Woods, for the purposes of a water supply for the city of Winnipeg.

Quebec, Que.—The legislative assembly unanimously voted the third reading of the Ottawa water bill on December 19th, with two amendments, one to translate into French the title of the bill, the other to replace clause nine by the following:—"The lands acquired or possessed in consequence of the coming into force of this act, shall not be subject to municipal taxes except in the same proportion as those imposed on other lands in the same municipality. Provided, however, that as soon as water will be furnished to the city of Hull in the manner provided in section 5 of the present law, all lands acquired or possessed in the city of Hull in consequence of the coming into force of the present law will become exempt from municipal and other taxes for ever, but the buildings and pipes for the purposes of this act shall for ever be exempted from all municipal and other taxes."

Stamford, Ont.—The contracts have not been awarded for water pipes and pumps, these being held over by council for further consideration. The engineer was instructed to enquire into the stability of steel pipe, and it is probable that this contract will be left to the new council for award.

+—**Stamford, Ont.**—The Stamford council met recently and awarded the contract for 6, 8, and 10-inch valves to the CANADIAN FAIRBANKS MORSE COMPANY, of Toronto.

+—**Stamford, Ont.**—The municipal council has awarded to the DARLINGTON PUMP MANUFACTURING COMPANY of Williamsport, Pa., for hydrants at a tender of $33.80 per hydrant.

+—**Toronto, Ont.**—The board of control has awarded a contract for 12-inch pipe to the CANADIAN ALLIS-CHALMERS COMPANY, and for 6-inch pipe to the NATIONAL TUBE COMPANY of Pittsburg, Pa.; the contracts to involve an expenditure of about $90,000.

Toronto, Ont.—The board of control has accepted contracts for approximately $200,000 worth of sewer construction in various parts of the city, including Moore Park, Danforth Avenue (from Hillingdon Avenue to Woodbine Avenue), Annette Street, and Woodbine Avenue.

Victoria, B.C.—As a result of negotiations with the Esquimalt and Nanaimo Railway officials, a by-law for the gradual acquisition of the Leech River watershed at a reduced figure—e.g., $142,050 less than the original offer—is to be considered by council when further information has been obtained upon the subject from experts.

Victoria, B.C.—The South Vancouver Municipal Council has sent a deputation to meet the provincial executive in connection with its water records proposals covering Seymour Creek for the announced purpose of constructing a water system of its own, and claims that several private records on the creek should be cancelled by the government as they are not in use. The South Vancouver representatives claim that the records held by the city will not be in any way interfered with and that there will be sufficient water to cover for Vancouver and South Vancouver records.

Winnipeg, Man.—Tenders will be received up till January 9th for the supply of a quantity of cast-iron water pipe (class "C"), and specials for the domestic waterworks system. Plans and specifications may be obtained from the City Engineer, 223 James Avenue, Winnipeg, Man. Signed, M. Peterson, Esq., Secretary, Board of Control.

Winnipeg, Man.—Tenders will be received up till January 2nd for the supply of 300 6-inch valves for the domestic waterworks system. Plans and specifications may be obtained from the City Engineer, 223 James Ave., Winnipeg, Man. Signed, M. Peterson, Esq., Secretary, Board of Control.

LIGHT, HEAT AND POWER.

Ayr, Ont.—The farmers of the Roseville and New Dundee districts are asking for information and estimates from the Hydro-Electric Commission for the supply of power for farm labor purposes.

Calgary, Alta.—On the recommendation of the commissioners the council has approved the tender and let a contract to the KILMER, PULLEN & BURNHAM COMPANY for a motor generator set at $18,250.

Calgary, Alta.—The city council has agreed to a recommendation of the city commissioners making an agreement with the Bowness Estates Company to supply current to the Bowness line of street cars for a term of three years at 2 cents per kilowatt hour.

London, Ont.—The board of trade has appointed a subcommittee to investigate the natural gas situation. The committee is to secure first-hand information from Windsor, Chatham and other natural gas-using municipalities, and will report at the next meeting of the board.

Prince Rupert, B.C.—The city council decided at its last meeting to submit a by-law to municipal electors on the hydro-electric scheme.

Wilkie, Sask.—The town council has considered and will further consider the placing of a by-law before the people of Wilkie to raise $30,000 for the extension and development of the electric light service here. This will include the installation of an additional engine to produce a greater supply of electrical energy for consumption by the residents in a private capacity and later to supply motive power for various industries.

Winnipeg, Man.—Tenders will be received up till January 5th for the supply of pole type and subway transformers required during the year 1914. Plans and specifications may be obtained from the office of the City Light and Power Department, 54 King St., Winnipeg, Man. Signed, M. Peterson, Esq., Secretary, Board of Control.

Winnipeg, Man.—Tenders will be received up till January 29th for the manufacture and delivery of electrically operated switching apparatus and accessories for the King Street substation. Plans and specifications may be obtained from the

The Superiority of

CYCLONE CHAIN HOISTS

Increases With The Size

The ingenious eccentric gyrating gears, used only on "CYCLONE" Chain Hoists, give so great a speed reduction, in so compact and simple a form, that the superiority of the "CYCLONE" becomes more marked with every increase in capacity.

In sizes from three tons up, the "CYCLONE" is lighter in weight, much more compact, has fewer pendant chains, and a shorter distance between hooks than other hoists. This, of course, makes it much more convenient for practical work.

In addition, the "CYCLONE" has self-lubricating graphite-bronze bushings, an exceptionally smooth-working and efficient brake, and a higher efficiency, particularly in the larger sizes, than any other hoist made.

We are prepared to ship direct from any of our four warehouses.

BRIDGES, ROADS AND PAVEMENTS.

Assiniboia, Man.—At the final meeting of the Assiniboia council for 1913, notice was given of a motion to rescind the contract awarded to the Bitulithic Company for the construction of 7 miles of pavement from Kirkfield Park to the western boundaries of the municipality. This has the effect of holding up the signing of the contract by the present council, and leaves the matter to be dealt with by the new council, which takes office on January 7th, 1914.

Berlin, Ont.—At the recent special sitting of the Highways Commission in Berlin, representatives of Waterloo County give as their opinion that the extent of Government aid given towards the construction of good roads throughout the province should be two-thirds of the cost, as well as a share of the maintenance of improved highways. It was also urged by farmers that, not trunk roads, but good township roads to nearest markets and shipping points, was what was needed in the province.

Brantford, Ont.—The civic Board of Works has decided to make application to the Railway Board for two subways at the intersections of the Grand Trunk Railway with Market Street and St. Paul's Avenue respectively.

Medicine Hat, Alta.—A subway at River Street at a total cost of only $75,000, including both steel and concrete work, is the proposition which McCoy and Levine, in conjunction with the contracting firm of Grace, Higdon and Kerr, put before the city council recently. It was referred to the public works committee to be dealt with at a future adjourned meeting of the council.

Moose Jaw, Sask.—The question of securing financial aid from the provincial government, from the cities of Moose Jaw and Regina and from the intermediate municipalities towards the cost of a highway to be built between the two cities, is being taken up by the Regina Automobile Club. The club will doubtless receive the co-operation of the civic board of trade.

North Vancouver, B.C.—The district council has endorsed the proposal for a driveway up the North arm, connecting Keith Road with Indian River. The secretary of the Seymour and North Arm Ratepayers' Association wrote stating that the public works department wished to be advised of the estimated cost of same, so that the road superintendent of the association could make a report on it before the estimates for next year were made. Engineer Cosgrove was instructed to forward this estimate, which will show approximately $200,000. It is understood further that the government is considering a road from North Vancouver to the Squamish, the alternate route being up the Seymour River.

Prince Albert, Sask.—A definite announcement has been made by the Hon. J. H. Calder, Minister of Railways in the Saskatchewan Legislature, to the effect that actual work on the Grand Trunk Pacific bridge over the South Saskatchewan River will be commenced within thirty days. The government intends giving the company a further guarantee of $2,000 per mile for railroad construction, and in addition $1,300,000 to cover the cost of two railway bridges, one of which is on the line from Young to Prince Albert. It is expected that a time limit will be placed on the construction of the South Saskatchewan bridge in order that no delays may take place.

St. Johns, Que.—The Provincial Government has acceded to the demand of a delegation from the town council respecting the construction of a free bridge between St. Johns and Iberville, and a bill presented by Hon. Mr. Taschereau is now before the Legislature proposing that the Government undertake the construction and take over the amount voted by the municipalities of St. Johns and Iberville, and also the Dominion Government grant.

Toronto, Ont.—The Harbor Commissioners have approved plans for a lift bridge of the "scissors type" to be erected over the Don River at Cherry Street next spring, at a cost of $294,000, the lift span to be 86 feet.

Vancouver, B.C.—The Kilsilano-Burrard Street Bridge Association has formed again to endeavor to bring once again before the people of the city the scheme for the erection of a bridge between the end of Burrard Street and a point on the Kitsilano Reserve.

Windsor, Ont.—Essex County Council has definitely refused to vote on the proposed by-law to expend $1,000,000 on a chain of good roads throughout Essex County and the by-law will not be considered at the January elections.

INDUSTRIAL WORKS.

A—Nassau, Ont.—Tenders will be received up till December 31st for excavation and dredging in the tail race of the power plant of the Canadian General Electric Company, Limited, at Nassau, about 6 miles from Peterborough. Plans and specifications may be seen at the offices of the company at Toronto, or at Peterborough; or at the office of Henry Holgate, Consulting Engineer, Richelieu Building, Montreal, Que.

Ottawa, Ont.—Tenders will be received up till January 12th for the construction of the substructure and approaches of a highway bridge at North Timiskaming, County of Pontiac, Que. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. Signed, R. C. Desrochers, Secretary.

St. John, N.B.—As a result of the fact that No. 9 crib of the new Sand Point wharf broke off below low-water, it may be necessary to tear out the remaining section, and to construct an entirely new crib. The extent of damage to No. 10 crib, recently overturned partially by the tide, is not yet known; but it is generally believed that the complete construction of two new cribs will have to be undertaken.

+—Thornbury, Ont.—The contract has been awarded by the Dominion Government to N. B. HORTON and J. D. STODDART, of Owen Sound, for harbor improvements at Thornbury, Ont., to cost $15,844.55.

Vancouver, B.C.—The civic bridges and railways committee, at its last meeting, heard the report of Engineer A. P. Hueckel, who is in charge of the East End viaduct. He reported that the plans had not yet been received from the Great Northern Railway at St. Paul. He was instructed to write the head office making the request that they be forwarded as soon as possible. The city engineer was ordered to go ahead with the plans of the retaining wall in False Creek for submission to the Harbor Board.

MISCELLANEOUS.

+—Edmonton, Alta.—The contract has been awarded to the ROBERT & SCHAEFER CO., of Chicago, by the Brazeau Collieries, Limited, to install a plant of 2,000 tons daily capacity on its property at Nordegg, 120 miles west of Blackfalds, on the C.N.R. branch from Stettler, Alta. The plant is to be in operation by next September.

Montreal, Que.—The plants of the Canadian Car and Foundry Company, and plants of its subsidiary companies, were closed on December 20th, and will not be opened until after the first of the New Year, the object being to go over the entire equipment and to make all necessary repairs.

St. John, N.B.—Mayor Frink has devised a means for providing a site for additional piers in St. John harbor. A large area of water front on the eastern side of the entrance to the main harbor, adjoining the Ballast wharf property, is lying practically idle, and its usefulness is destroyed by an I.C.R. trestle which crosses the property. The Mayor suggests that the trestle be moved back and thus room would be provided for two large steamer berths, which could be erected with very little preliminary work.

Victoria, B.C.—Tenders have been called for December 27th in connection with the work on the Hudson Bay Company's new store at Victoria, and work is to commence by January 15th. Some of the works for which separate tenders are called, are reinforced concrete, plain concrete, sheet metal work, ornamental iron, architectural terra cotta, etc. The first four stories of the building will be erected at a cost of $450,000.

PROTECTED PRESSURE REDUCING VALVE

When the pressure on the outlet rises above the pressure at which the valve is set to work, the valve closes. The valve opens again when the pressure falls below that point. The pressure on outlet may be increased by tightening the spring or diminished by releasing it. In the smaller sizes the spring is fitted with a screwed cap instead of crosshead. With this valve the water is shut off absolutely tight. In the event of fire, full pressure is obtained by screwing down the spring to its limit.

MONTREAL TORONTO VANCOUVER

CURRENT NEWS.

Beaton, B.C.—Good progress is reported on the construction of the floating wharf at Beaton.

Brantford, Ont.—On January 15th at Brantford Hydro-Electric current will be turned on for ornamental street lighting purposes, and February 1st, for the use of domestic and commercial lighting purposes.

Brantford, Ont.—Dr. F. G. E. Pearson, M.H.O. for Brantford, gives it as his opinion that a big artificial gas plant will be located on Lake Erie, where coal haul is cheap, and will supply a chain of municipalities in the southern part of western Ontario through the pipes now laid and being laid for natural gas, which, he claims, will not last forever. The Dominion Gas Company, in furnishing the Kent product at Brantford, already has claimed danger of a shortage in the Haldimand field.

Brantford, Ont.—Brantford's lighting rates under the Hydro-Electric will be about half the present rate charged by the Western Counties Company. The present electric light rate is 8½ cents per kilowatt. The new Hydro rate will be 3½ cents per kilowatt and 4 cents per 100 square feet of floor space.

Delhi, Ont.—The prospects for securing sufficient contracts for the required waterworks revenue of $2,000 at Delhi, are very encouraging.

Fort William, Ont.—The work to be carried out next year in the Mission river, and for which tenders have been received at the Department of Public Works, Ottawa, covers the construction of quay walls of 2,646 feet total length, in two parts, of 1,225 feet and 1,421 feet respectively. The construction is to be of square timber crib work, close faced on the outer faces and open faced on the inner faces, the outer faces to have a batter of 1 in 24, and the other faces to be vertical. When fully ballasted the top of the crib work is to be six inches below low water level. The superstructure is to be of concrete, and when completed to be 5.5 feet above low water level. The site will be dredged to a depth of 26 feet at low water.

Fredericton, N.B.—Warden W. R. Fawcett, of Temperance Vale, has just completed the construction of three bridges in the province, the Jones Creek Bridge, Malone Bridge at Sussex, and the Smithtown Bridge. The largest of these is the Jones Creek Bridge, erected at a cost of $8,000. All the bridges are completed with the exception of the roofing in, which will be done in the spring.

Fort William, Ont.—It is expected that steel will be laid to connect up the new line of the C.N.R. between Port Arthur and Sudbury by the beginning of the year, according to the statement of A. J. Isbester, resident engineer. At present there are 18 miles on which the steel is to be placed, and all grading is completed.

Hamilton, Ont.—The city council has decided to let the matter of the C.N.R. level crossing on Waterdown Road stand over until all possible information has been presented to council.

Kimberley, B.C.—Work is progressing favorably on the new power plant that is being installed by the Consolidated Mining and Smelting Company at Sullivan Siding, and in the course of a few weeks the air compressor will be run by steam power furnished by two steam boilers instead of water power as at present.

London, Ont.—The increase in the consumption of power at London was responsible for the stringing of a third feeder recently. Also, work is progressing night and day for the supply of the London Street Railway with Niagara current.

Montreal, Que.—The Northern Railway has completed the preliminary survey of 170 miles between Calumet and Belle River on the G.T.P., and it is expected to start construction work in the spring.

Moose Jaw, Sask.—The new C.N.R. branch line from Avonlea to Gravelbourg has been handed over by the contractors to the company, and it is anticipated that this will be in operation within a short period.

New Hazelton, B.C.—The Stewart Brothers have completed their contract at Burns lake, and have shipped part of their plant to Fraser lake. Since April, they have moved over 800,000 yards of rock and earth, employing in the work a large force of men, several steam shovels, and several donkey engines.

North Vancouver, B.C.—In connection with the acquiring by the city of the Rice Lake lands for watershed purposes, the government sent a message to the city council to the effect that it would have to defer further its decision until a conference could be held with the district council and the British Columbia Electric Railway Company, the other two parties interested in the right to purchase.

Ottawa, Ont.—Work is advancing rapidly on the new Welland Canal and section 8 will be the next section for which tenders will be called. This is the section next to Port Colborne, and will be an expensive cut as it is through rock for the most part. Plans and specifications are now in preparation and tenders will be called for during the winter.

Ottawa, Ont.—Seven of the hydro-electric companies operating under Dominion charters, generated 191,986 horse-power during the last fiscal year, and of this amount 101,423 horse-power was exported to the United States, while 90,462 horse-power was used in Canada. The points of export are Fort Frances, Niagara Falls, Aroostock Falls, N.B., and Vancouver. The chief exporting companies are the Canadian Niagara Power Company, which sold 49,850 horse-power in the United States, in contrast to 1,682 horse-power used in Canada, and the Ontario Power Company, which exports 38,912 horse-power, in contrast to 43,503 horse-power used on this side of the line.

Ottawa, Ont.—There has been spent to date $153,000,000 on the National Transcontinental Railway and the Quebec Bridge. The steel-laying on the main line between Moncton and Winnipeg was finished just a month ago, but about $17,000,000 will be needed to complete the road for actual operation.

Ottawa, Ont.—G. A. Mountain, chief engineer of the railway commission, and Assistant Engineer Simmons have inspected the C.N.R. Ontario Railway from Ottawa to Napanee, which has recently been completed, and which is a continuation of the Toronto-Napanee line. The line is in good condition, and will be opened for freight and local passenger traffic on January 5th. Through service will begin in the spring. Splendid steel bridges have been constructed and preparations are being made for the manning of the stations along the line.

Ottawa, Ont.—The new government wireless stations at Toronto and Port Burwill are now practically completed, and will be ready for operation at the beginning of the new year. They will afford wireless communication for the railway ferries plying all winter on Lake Ontario and Lake Erie. Next spring the station at Kingston will be opened, giving connection right through to Montreal and completing the chain from the head of the lakes to Belle Isle.

Ottawa, Ont.—It has been learned with authority that the Canadian Northern Railway Company will be the owner of the Quebec and Saguenay Railway within a few days; and an official statement will be issued as to the outcome of negotiations in progress at Ottawa.

Peterborough, Ont.—A. B. Colville, Vice-President of the Peterborough Light and Power Company, has sent a letter to the City Clerk, stating that in the event of the city of Peterborough not having obtained possession under the Hydro expropriation by-law of the plant of the company by January 1st, 1914, the company would be pleased to continue lighting the streets of the city at the same rate as under the company's street lighting contract expiring December 31st, 1913, and to continue to do so till the city gets possession.

Peterborough, Ont.—The price at which the Otonabee Power Company will sell to the city has been fixed at $48,000. It is probable that an arrangement will also be made whereby the franchise of the company will be extended from month to month until the city will be in a position to supply power to the customers now served by the Otonabee Power Company.

Peterborough, Ont.—The contractors who are building the C.P.R. bridge across the Otonabee River expect to have the structural work complete by Christmas, but the middle span, which will be a swing section, will not be erected till the fall. This is due to the fact that a swing bridge was not demanded until the plans for a stationary bridge had been completed. Contractors will construct what is technically known as a bobtailed swing, which will provide a thirty-seven foot channel.

The Departmental House for Mechanical Goods HAS ARRIVED

What the department stor is to the general public our "Mechanical Goods Departmental House" is to the engineering and contracting field.

The public takes the efficient and time-saving merchandising methods of the department store as a matter of course. In the mechanical world we offer the same convenient service.

Why lose time "shopping" around town when you can buy anything you want and of a standard quality all under "one roof"?

Our business is divided into a number of departments in order that it may be handled most expeditiously and to the best interests of our customers.

In addition to the staple articles pertaining to each department we handle a great many specialties, some of which are listed below

SCALE DEPARTMENT
- Fairbanks World-famous Scales, of all types and sizes

VALVE and STEAM GOODS DEPARTMENT
- Fairbanks Brass and Iron Valves
- Pratt and Cady Valves
- Foster Reducing Valves
- American Steam Pressure Gauges
- Wainwright Joints
- Penberthy Oilers
- Strong Steam Traps
- Wainwright Heaters
- Burt Exhaust Heads
- American Safety Valves
- Trident Water Meters
- Palmetto Packing
- Durabla Packing
- Oster Stocks and Dies
- Tools and Fittings

ENGINE DEPARTMENT
- Fairbanks-Morse Oil Engines
- Fairbanks-Morse Marine Engines
- Fairbanks-Morse Tractors
- Farm Machinery
- Motor Boat Supplies
- Automobile Supplies

PUMP DEPARTMENT
- Fairbanks-Morse Steam Pumps
- Power Pumps
- Goulds Power Pumps
- Hand Pumps
- Combined Engines and Pumps
- Spraying Outfits
- Air Compressors
- Suburban Water Systems

ELECTRICAL DEPARTMENT
- Fairbanks-Morse Generators and Motors
- Edison Storage Batteries
- Suburban Lighting Outfits

MACHINERY DEPARTMENT
- Pratt and Whitney Tools
- Brown and Sharpe Tools
- McDougall Lathes
- Bertram Tools
- Machine shop tools of all kinds
- Wood Working Machinery

TRANSMISSION DEPARTM'T
- Fairbanks Wood Split Pulleys
- Universal Giant Shaft Hangers
- Skefko Ball Bearings
- Nicholson Couplings

RAILWAY and SUPPLY DEPARTMENT
- Fairbanks-Morse Motor Cars
- Elwell-Parker Trucks
- Barrett Jacks
- Arthur Koppel Industrial Ry. Equipment
- Fairbanks-Morse Air Compressors
- Fairbanks-Morse Hoisting Engines
- Fairbanks Trucks
- Milburn Lights
- Smith Concrete Mixers

SMALL TOOL and SUPPLY DEPARTMENT
- Pratt and Whitney Tools
- Brown and Sharpe Tools
- Yale and Towne Hoists
- Alundum Grinding Wheels
- Crystolon Grinding Wheels
- India Oil Stone
- Parker Vices
- Union Chucks

SAFE and TYPEWRITER DEPARTMENT
- Dominion Safes and Vaults
- Noiseless Typewriters

TRUCK DEPARTMENT
- Mack Trucks (gasoline)

TENDERS CALLED FOR

Sealed tenders addressed to the undersigned, and endorsed "Tender for Submarine Cables," will be received at this office until 4 p.m., on Thursday, the 15th January, 1914, for 10 knots of gutta-percha cable with 4 conductors and 14 knots of gutta-percha cable with 2 conductors to be delivered at Halifax., N.S., or St. John, N.B., by the 1st of May.

Specification and forms of tender can be obtained on application to the office of the General Superintendent of the Government Telegraph Service at the Department of Public Works, Ottawa.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 per cent.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, December 9, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—51974.

TENDERS FOR DREDGING.

The undersigned will receive tenders up to December 31st, 1913, for excavation and dredging in the tail-race of their Power Plant at Nassau, about six miles from Peterborough. The estimated amount of material to be removed is 24,000 cubic yards. Plans and specifications may be seen at the offices of the Company, either at Toronto or Peterborough, or at the office of Henry Holgate, Consulting Engineer, Richelieu Building, Montreal. Lowest or any tender not necessarily accepted.

CANADIAN GENERAL ELECTRIC COMPANY, LIMITED.

CITY OF OTTAWA, DOMINION OF CANADA.

TENDERS FOR STEEL PIPES.

Sealed tenders in duplicate addressed one copy to the City Clerk, City of Ottawa, Canada, and the other to Sir Alex. Binnie, Son and Deacon, St. Stephens House, Westminster, London, England, and endorsed, "Tenders for steel pipes," will be received until 4 p.m. on Tuesday, the 3rd day of February, 1914, for about forty-two miles of steel pipe, fifty-four inches internal diameter, about thirty-two miles of steel pipe, fifty-eight inches internal diameter, and about eleven miles of steel pipe, fifty-one inches internal diameter.

Forms of tender and specification may be obtained from Sir Alex. Binnie, Son and Deacon, St. Stephens House, Victoria Embankment, London, S.W., or from the City Engineer of Ottawa, Canada, on and after the fifteenth, on receipt by them of a cheque to the value of five hundred dollars, made out to the City Treasurer of the City of Ottawa, Canada, which sum will be returned on receipt of a bona fide tender.

The lowest or any tender is not necessarily accepted.

No tenders will be considered except from actual manufacturers capable of supplying the whole of the pipes within a period of two and a half years from the date of acceptance of the tender.

SIR ALEX. BINNIE, SON & DEACON,
Engineers in Chief,
St. Stephens House,
Westminster, London.

Dated December 4th, 1914.

NEW INCORPORATIONS.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria St., London, S.W.:—

A Canadian firm makes inquiry for names of United Kingdom manufacturers of sheet zinc, 36-in. x 8-in., No. 9 gauge; 48-in. x 8-in., No. 9 gauge; and 60-in. x 8-in., No. 9 gauge.

From the branch for city trade inquiries, 73 Basinghall St., London, E.C.:—

A London dealer in electrical supplies, who claims a large connection with consumers of amber mica, would be glad to act for Canadian producers upon a commission basis. A London firm with several continental branches, who specialize in insulating materials, are open to consider offers of high-class Canadian amber mica, and invite quotations from Canadian shippers.

TRANSPORTATION BUILDING — MONTREAL

MONTREAL MARKET LETTER.

There is absolutely no interest whatever in the iron and steel situation here from the standpoint of trading. The holiday spirit prevails, and no one is talking about anything save Christmas. There is no buying whatever of iron and steel, and merchants are not making any attempt to do business, knowing that such would be futile. These remarks apply not only to the present week, but will apply to the following week and possibly to several weeks thereafter. In fact, the general view expressed by merchants here is that no one need look forward to any new business of consequence until well into January, and possibly until after the first of February.

Industrial undertakings which call for large expenditures on iron and steel are for the most part dependent upon the financial situation; and the financial situation is in turn dependent upon conditions outside of Canada, so that it becomes necessary at the present time to wait upon financial developments on the other side of the Atlantic. Reference is now more especially made to Paris, upon which centre the eyes of financiers are at the moment turned. It is expected that some large flotations are to be made in Paris very shortly and the manner in which these are taken will give a fair indication of the general situation. An enormous amount of financing is pending throughout Europe, and much is also pending in the United States. Meantime, expenses in Canada are being cut every day, so that, unless it turns out that there is more money abroad than is thought to be at the moment, it seems likely that demands for iron and steel will not reach very large volumes for some time to come. This, naturally, has an effect also upon prices. These are holding extremely steady, being at a low level. No changes of prices are taking place, largely for the reason that few are making any effort to buy and very few offers are being received.

A number of the larger works are either closing down or operating on short time, and it is likely that others will adopt a similar policy before long.—Montreal, December 23rd.

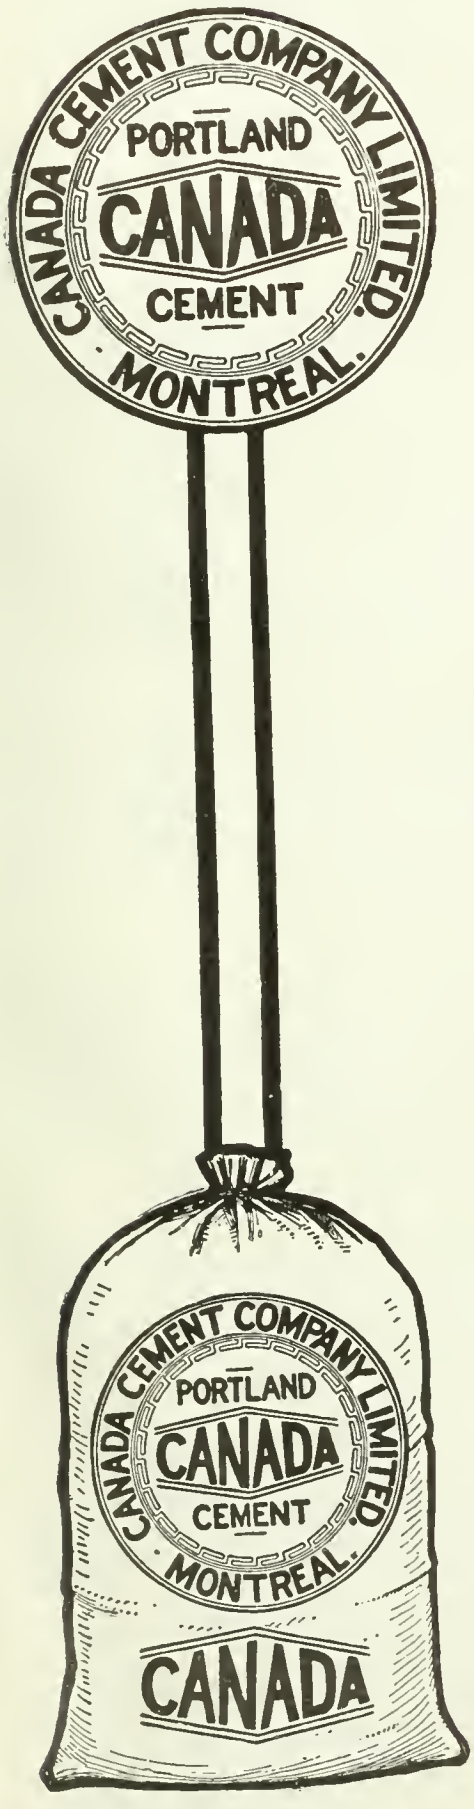
PERMANENCE—



an ideal that is now attainable

THE superiority of concrete over all other materials for the building of permanent structures is now generally adm ted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

WANTED.

Ontario Land Surveyor to act as Corporation Surveyor for the City of Port Arthur.

Applications will be received by the undersigned up to January 20th, 1914.

Applicants should state experience and salary expected.

L. M. JONES,
City Engineer.

ONTARIO LAND SURVEYOR required for general work in Toronto and suburbs, one having had experience in estate subdivision work. Permanency for good man. Apply stating age, and salary expected, to Box 198, *The Canadian Engineer*, Toronto.

MECHANICAL DRAFTSMAN.—Location, Toronto, with first-class experience in design of special equipment, conveying machinery, ore and coal chutes and gates, and capable of successfully designing mechanical operations from suggestions of the Engineer. Preference given to man who has a knowledge of large steam piping. Applicants to state age, name, references, and give a full outline of experience, names of firms where this experience has been gained, which will be treated confidential. Address Box 200, *The Canadian Engineer*, Toronto.

STRUCTURAL STEEL DRAFTSMAN.—Location, Toronto, capable of accurately designing and detailing industrial plant buildings, and special structures in connection with conveying machinery. Preference given to man familiar with special steel plate structures. Reply stating age, describe fully experience and mention references to Box 202, *The Canadian Engineer*, Toronto.

ARCHITECTURAL DRAFTSMAN.—Location, Toronto, experience in design and detail of industrial plant buildings essential. Reply stating age, experience, and describing some of the work carried to completion, and name references. Address Box 204, *The Canadian Engineer*, Toronto.

A1 TRACER.—Location, Toronto. Must be first-class letterer, rapid and accurate. Applicants to state age, describe fully experience and submit samples of lettering. Address Box 206, *The Canadian Engineer*, Toronto.

Despatches from London say that parliament will be asked to sanction a huge project next year for supplying electricity in bulk to London by a private enterprise. The company will undertake the electric lighting and the power supply of London now carried on by the Electric Lighting company and will provide a great central station, which will be equal, if necessary, to providing electric power for railways. Several railways, notably the Midland, the London and Northwestern, and the Great Northern, at the present time have important electrification projects in hand, and Mr. Guy Garnet, general manager of the Midland railway, is in America studying the electrification question.

MARKET CONDITIONS

Montreal, December 22nd, 1913.

Bar Iron and Steel—Trade is reported active. Bar iron, $2.05 per 100 pounds; best refined horseshoe, $2.30; forged iron $2.20; mild steel, $2.15; sleigh shoe steel, $2.15 for 1 x ⅜ base; tire steel, $2.25 for 1 x ⅜ base; toe caulk steel $3; machine steel, iron finish, $2.25.

Cement—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in. $4.70; ⅜ in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3.45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1-in., $3.05.

Explosives and Accessories—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25 lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength per 100 fuses:—4 ft. wires, $3; double strength, $3.50; 6 ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4.30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $21.75 per ton; selected Summerlee, $21.25; soft Summerlee, $20.75 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19 to $19.50 per ton, on track.

Lath—See Lumber, etc.

Lumber, etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph poles: seven-inch top, cedar poles, 25-ft. poles, $2, each; 30 ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths at manufacturers' points. Spruce 4-ft. x 1½ in., mill run, $3 to $3.25; pine 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Pipe—Cast Iron—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe—Wrought and Galvanized—Demand is fair and the market steady: —¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. off for galvanized: 3½-inch $95 4-inch, $1.08.

Toronto, December 24th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes—Orders continue active. Lap-welded, steel, 1¼-inch, 10c. 1½-inch, 9c. per 10-ft.; 2-inch $8.50 to $9; 2½-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $14 to $15 per M., three grades.

Broken Stone—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch or larger, price all the same. Rubble stone, 55c. per ton. Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto 60 cents.

Cement—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks, 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps—75c. and $1 per 100; case lots, 5,000, 20 per cent. off.

Dynamite—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents per pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10 case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cents.

Fuses—Electric Blasting—Double strength, $3.50 per hundred, advance 5c. per hundred for each 2 in. wire additional. Single strength, $3 per hundred, advance 5c. per hundred for each 2-in. wire additional.

Iron Chain—¼-inch, $5.75; 5-16-inch, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞ inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch $6.19; 1½-inch, $7.43; 2 inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanized Pipe, ¼-inch, $2.86; ⅜-inch, $2.86; ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead—Firmer, $5.25 to $5.50.

Pig Iron—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1914.

Pitch and Tar—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green $8, with a prospect of advance. Dealers are fairly busy.

Sand—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0 25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1 60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes 9 inches and under, or less 60 per cent. off these figures on anything over 19 inches. For car-loads a greater discount.

Steel Beams and Channels—Active—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 lbs. Extra for smaller sizes of angles and tees.

Sheet Copper—22c. per lb.

Sheet Steel—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized—Apollo Brand—Sheets, 6 or 8 feet long, 30 or 36 inches wide: 10-gauge, $3; 12-14-gauge, $3; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 lbs. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin—The combination seems to hold, and the price 45 to 50c. lower.

Tool Steel—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates—3-16 inch, $2.40 per 100 lbs.

Zinc—Spelter—Good demand, and the feeling strong. Light stock; excelle demand. We quote very firm at $6 to $6.50 per cwt

Winnipeg, December 23rd, 1913.

Anvils—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¼ to 10¾c., anvil and vise combined, each $5.50.

Bar Iron—$2.50 base.

Bars—Crow $4.50 per 100 pounds.

Beams and Channels—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick—Kiln run per M, $13; sewer pipe per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland—$2.40 to $2.50 per barrel.

Chain—Coil, 3 16-in., $10; ¼, $7.25; 5-16, $5.65; ⅜ $5; 7-16, $4.75; ½, $4.50, 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper—Tinned, boiler, 26½c., planished, 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent. discount.

Dynamite—$11 to $13 per case.

Galvanized Iron—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90. Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30 22, $4.30; 20, $4.10 per cw

Iron—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75 24-gauge, $3.90; 26-gauge, $4; 28 gauge, $4.10. Galvanized—American 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26 gauge, $4.65; 28-gauge, $4.80; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English or 30-gauge American, $4.90; 30-gauge American $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe—Iron, black, per 100 feet, ¼-inch $2.40; ⅜-inch, $2.55; ½-inch, $2.85; ¾-inch $4; 1-inch $5.75; 1¼-inch, $7.80; 1½-inch, $9.35, 2-inch, $12.50; galvanized—½-inch $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled—3-16-in. $3.35 base; machinery, $3 base; share; $4.50 base; share crucible, $5.50; cast share steel, $7.50; ice caulk, $4.50 base; tire steel, $3 base; cast tool steel, 11c., 9 to 12½c.

Tool Steel—8½ to 15c. per pound.
